Sucrose (copper reduction method)	7.3
Crude fiber	0.0
Carbohydrates other than crude fiber (by difference)	0.4
Calcium (Ca)	8.2
Phosphorus (P)	0.01
Iron (Fe)	0.03
Copper (Cu)	0.0016
	0.00019

Calories — 0.4 per gram 11 per ounce

Claims of Manufacturer — An excellent source of vitamin C, and good in vitamins A and B. Specially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving.

I G A VEG-ALL FOR SOUPS, SALADS, VEGETABLE DISHES

Distributor — Independent Grocers Alliance Distributing Company, Chicago

Packer — The Larsen Company, Green Bay, Wis.

Description — Mixture of carrots, potatoes, celery, green beans, cabbage, peas, corn, lima beans, onions, sweet peppers, salt and water prepared by efficient methods for retention in high degree of the natural mineral and vitamin values of the respective vegetables. No added sugar or salt. The same as Larsen's Veg-All "A Magic Garden" for Soups, Salads, Vegetable Dishes (THE JOURNAL, Aug 12, 1933, page 525).

(a) MINNEOPA BRAND GOLDEN SYRUP

(85 PER CENT CORN SYRUP, 15 PER CENT
REFINERS SYRUP)

(b) MINNEOPA BRAND CRYSTAL WHITE SYRUP

(85 PER CENT CORN SYRUP, 15 PER CENT
GRANULATED SUGAR SYRUP)

Distributor — L. Patterson Mercantile Company, Mankato, Minn.

Packer — Penick and Ford Sales Company, Cedar Rapids, Iowa

Description — (a) The same as Penick Golden Syrup (Corn Syrup and Sugar Refiners' Syrup), THE JOURNAL, April 2, 1932, page 1159.

(b) The same as Penick Crystal White Syrup (Corn and Cane Sugar Syrups), THE JOURNAL, April 9, 1932, page 1268.

Claims of Manufacturer — Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

OSCAR MAYER'S APPROVED BRAND LIVER SAUSAGE

OSCAR MAYER'S BRAUNSCHWEIGER STYLE LIVER SAUSAGE

Manufacturer — Oscar Mayer and Company, Inc., Chicago

Description — Cooked and smoked sausage containing United States government inspected and passed ground pork livers and muscle, ground pork skin, powdered skim milk, onions, salt, pepper, mace, and annatto color.

Manufacture — Pork skins are cooked for two hours at 88 C, drained, ground and chopped with formula proportions of fresh pork livers and lean pork muscle (United States Government Inspected and Passed), dried milk, onions and spices. The sausage meat is stuffed into hog casings of 30 inch lengths which are tied off and cooked in water containing annatto color at 75 C until the internal temperature of the sausage reaches 68 C, well above that (58 C) required to kill trichinae. After chilling, the sausage is smoked for four hours at 40 C branded

and individually wrapped or packed in solid fiber boxes. The manufacture is under government inspection.

Analysis (submitted by manufacturer) —

Claims of Manufacturer — United States government inspected and passed.

CURDOLAC COMPANY BRAN, SOYA BEAN, INDIA GUM BREAKFAST PREPARATION

(ADDED SALT, BAKING SODA, SWEETENED WITH
SACCHARIN AND FLAVORED)

Manufacturer — Curdolac Food Company, Waukesha, Wis.

Description — Short strands of a preparation of starch free wheat bran, roasted soy bean, India gum, sodium chloride, sodium bicarbonate, sweetened with saccharin and flavored with cassia extract and vanilla.

Manufacture — Thrice ground Minnesota bran is treated with diastase to convert the starch to soluble carbohydrates, is washed with water, and dried. Cleaned soy beans are roasted to the desired flavor and ground. Definite proportions of washed bran, roasted soy bean flour, India gum, salt and sodium bicarbonate are mixed, water, saccharin and flavoring are added. The dough mass is run through a mill to form strands, which are spread on baking sheets, dried, and packed in cartons.

Claims of Manufacturer — "Special purpose food for diets low in carbohydrates. Provides bulk. Use under the directions of a physician."

LIGHT'S OVEN-PERFECT BISCUIT FLOUR READY MIXED

Manufacturer — The Light Grain and Milling Company, Liberal, Kan.

Description — Biscuit flour containing bleached hard winter wheat short patent flour, hydrogenated cottonseed oil, skim milk, sucrose, sodium chloride, sodium bicarbonate, sodium acid pyrophosphate, and calcium acid phosphate.

Manufacture — The ingredients are mixed in definite proportions in a batch mixer and automatically packed in wax paper lined cartons.

Analysis (submitted by manufacturer) —

LIGHT'S BEST OVEN PERFECT FLOUR, SELF-RISING (BLEACHED)

Manufacturer — The Light Grain and Milling Company, Liberal, Kan.

Description — Self-rising flour prepared from bleached hard winter wheat standard patent flour, sodium chloride, calcium acid phosphate and sodium bicarbonate.

Manufacture — The ingredients are mixed in definite proportions in a batch mixer and automatically packed in cotton bags. The flour is bleached with nitrogen trichloride (one seventh ounce per barrel).

MEDICAL LICENSURE STATISTICS FOR 1933

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The report herewith presented for the year 1933 deals with statistics regarding (a) medical licensing boards of the United States, including the District of Columbia and the territories and possessions of the United States, (b) basic science boards, and (c) the National Board of Medical Examiners. In the publication of these statistics, the endeavor has been to show the actual facts, a knowledge of which is always beneficial. The information should be of service to medical schools and licensing boards as well as to the public.

Official reports have been contributed by the officers of the medical licensing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii and Puerto Rico, three homeopathic boards (Connecticut, Delaware and Maryland), the eclectic board of Arkansas, the seven basic science boards in operation during 1933 (Arkansas, Connecticut, the District of Columbia, Minnesota, Nebraska, Washington and Wisconsin), and the National Board of Medical Examiners. Every effort has been made to insure accuracy. The officers of these boards deserve much praise for the completion of their reports, and acknowledgment is here made of their splendid cooperation. The officers of these boards also rendered the Association invaluable assistance in other respects by which we are continually able to improve the biographic records.

The tables showing medical licensing board results include figures regarding the number of candidates examined in 1933 for medical licensure, the number licensed and the number added to the profession.

LICENTIATES

Table 1 gives the actual number of licenses issued in the various states, territories and possessions during the year. There were 5,174 licensed on the basis of examination and 1,951 by endorsement of credentials. In several states (table 5) the internship is a requisite for licensure, but a physician is permitted to take the examination, his license being withheld. This is particularly true in Iowa and Michigan. Licenses are also withheld for lack of citizenship, fees or other minor technicalities. In consequence these are omitted in recording the number licensed. The figures, therefore, for those licensed after examination include many who were examined in 1932 and even a few in previous years. New York issued the largest number of licenses, 1,054, Pennsylvania issued 507, Illinois 460, California 417, Ohio 369 and New Jersey 309. All other states licensed fewer than 300. Only one physician was licensed after examination in Nevada, and New Mexico registered none by this method. Florida grants licenses only on the basis of examination. Massachusetts and Rhode Island have no reciprocity privileges but endorse diplomates of the National Board of Medical Examiners. A total of 7,125 licenses were awarded. This figure, however, does not represent 7,125 individuals since several have been licensed in more than one state during the year. Table 4 shows how many of those licensed were never before registered and, therefore, represent the number added to the medical profession.

TOTAL EXAMINED

Table 2 gives the results (passed and failed) for all candidates who took examinations in 1933. There were 5,658 examined, of whom 5,229 passed and 429 failed. These came from 67 approved medical schools in the United States and 9 in Canada, 59 medical schools of other countries, 14 medical schools now

extinct, 7 unapproved institutions and several osteopathic colleges. These statistics contain figures regarding only those osteopaths granted the privilege to practice medicine, surgery or both by the medical board. There were 5,040 graduates of approved medical schools in the United States examined, of whom 33 per cent failed, 122 Canadian graduates, 15.6 per cent of whom failed, 203 foreign graduates with 36.5 per cent failures, 16 who graduated from schools now extinct, with 50.0 per cent of failures, and 277 from unapproved and osteopathic schools, of whom 58.8 per cent failed. Of these 277, 82 were graduates of osteo-

(CONTINUED FROM PAGE 1385)

pathic schools, of whom 35 passed and 47, 57.3 per cent, failed, and 195 were graduates of unapproved schools, of whom 79 passed, and 116, 59.5 per cent failed. Graduates of osteopathic schools were examined in Colorado, Connecticut, Massachusetts, Texas and Wisconsin, while graduates of unapproved schools were examined in Arkansas (eclectic board), California, Delaware, Illinois, Massachusetts, Tennessee, Washington and Hawaii. Massachusetts licensed 53 and Illinois 38 of these practitioners.

The largest number of graduates of any one school represented was from Georgetown University School of Medicine, 166, which also had the highest number of failures, 22. These graduates were examined in 18 states. The University of Michigan Medical School had 152 graduates before 14 licensing boards, of whom 3 failed. The next highest number of graduates of any one school was Rush Medical College, which had 146 graduates examined in 26 states, of whom 2 failed. Graduates of Northwestern University Medical School and Rush Medical College were examined in 27 and 26 states, respectively. From these statistics one might infer that these schools educate more nonresidents than do other schools. Harvard University Medical School graduates were examined in 22 states and the University of Pennsylvania School of Medicine graduates in 23.

The one eclectic board in existence, in Arkansas, examined and licensed one candidate. The office of the state comptroller is at present conducting an investigation into the allegedly fraudulent issuance of licenses in Arkansas to eclectic doctors during past years. It is to be hoped that the desired results will be obtained.

Two of the five homeopathic boards in existence, Delaware and Maryland, examined ten candidates, all of whom passed.

In 1932, 5,663 were examined, of whom 5,235 passed and 7.6 per cent failed as compared with 5,658 examined in 1933, of whom 5,229 passed and 7.6 per cent failed. The figures, in general, compare equally with other years.

REGISTRATION BY RECIPROCITY AND
ENDORSEMENT

The number of physicians granted licenses to practice medicine and surgery without examination are given in table 3. There were 1,927 so registered who presented licenses from other states, Canada or foreign countries, the certificate of the National Board of Medical Examiners, one of the government services, or were registered on the basis of diplomas from foreign faculties of medicine.

In an increasing number of states the boards now accept a physician's credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. The following 29 states and the District of Columbia generally will register, without examination, licentiates who present satisfactory evidence of good moral character and practice record, and, in addition thereto, credentials which correspond to those required by their respective states at the time such licenses were issued.

Alabama	Maine	North Carolina
Arizona	Maryland	Oklahoma
California	Michigan	Oregon
Colorado	Minnesota	Pennsylvania
Connecticut	Missouri	South Carolina
Delaware	Nebraska	South Dakota
District of Columbia	Nevada	Texas
Georgia	New Hampshire	Utah
Idaho	New Jersey	Vermont
Illinois	New Mexico	Wisconsin

California (when ten or more years has intervened), Connecticut, Illinois, Minnesota and South Dakota require a practical or oral examination of reciprocity candidates, before a license is granted by this means. Applicants in Idaho are required to pass either a

Canal Zone Hawaii Puerto Rico and Philippine Islands (not complete)

written or an oral examination in medical jurisprudence as pertaining to practice in that state

Florida, Massachusetts and Rhode Island do not have reciprocal or endorsement arrangements with any state

New York granted the greatest number of licenses by endorsement of credentials in 1933 (307). New Jersey was second with 156, California third with 123, and Texas fourth with 105. The largest group representing the same type of credentials were the 391 diplomates of the National Board of Medical Examiners, the next greatest number (119) came from New York, Tennessee was third with 106, and Illinois fourth with 100.

Eleven physicians were licensed on the basis of Canadian credentials (Arizona 1 and New York 10) and 9 were registered by endorsement of foreign licenses (Germany 4, Great Britain 1, Mexico 1, Syria 1, and the Union of Socialist Soviet Republics 2). Two physicians were registered by endorsement of licenses issued in Alaska, two by Hawaiian credentials and one on the basis of a license issued in Puerto Rico. Sixteen physicians were licensed in New York on presentation of medical diplomas from Austria 3, Hungary 6, Italy 2, Rumania 1, Scotland 1, Switzerland 2 and Union of Socialist Soviet Republics 1.

The Eclectic Board of Arkansas registered one candidate by endorsement. One candidate each also was licensed by the homeopathic boards of Arkansas, Connecticut, Delaware and Maryland. In addition, 23 osteopaths were granted licenses to practice without examination. Thirteen so registered in Texas were granted privileges as physicians and surgeons while one in the District of Columbia and nine in Wisconsin were licensed to practice osteopathy and surgery. One nongraduate was registered without examination in Tennessee by a special act of the legislature.

CANDIDATES ADDED TO THE PROFESSION

In table 4 are recorded the number of candidates added to the profession during 1933. The number represents candidates examined in 1933 and licensed, also those examined in previous years whose licenses were withheld and issued in 1933, those certified on the basis of the certificate of the National Board of Medical Examiners, government services, Canadian and foreign credentials, and special exemption. In the main they represent recent graduates. Altogether, 5,012 were added to the profession as contrasted with approximately 3,500, the number removed by death in 1933. These figures indicate that some 1,500 have been added to the already overcrowded medical profession. It is interesting to note that, of 7,125 licenses issued throughout the year, 5,012, 70.3 per cent, are actual additions to the medical profession. The ratio is about twice as great as it is in England, France or Germany. The changing attitude of society toward the practice of medicine seems to indicate that in the future a smaller number of doctors may be able to render adequate medical service. The proper adjustment of the ratio of physicians to population is a matter of vital public concern.

The largest number added to the profession was in New York, 826. Pennsylvania added 411 and Illinois 394, Nevada and Wyoming added none and New Mexico only 1, Idaho 2 and Arizona 3.

STATE REQUIREMENTS OF PRELIMINARY EDUCATION

Although, for sixteen years, two years of premedical college training has been required by every class A medical school, there are still nine states which have failed to adopt this standard. Statutory requirements are shown in table 6 with the dates at which they

TABLE 3—Physicians Licensed by Reciprocity and Endorsement—1933

[illegible]

became effective. In chart 1 the same information is presented graphically.

COMPARISON WITH OTHER YEARS

In table 7 are listed the numbers of candidates examined in the various states, territories and possessions in the past five years, showing those who passed and failed. In this period New York examined 4,012 candidates, Pennsylvania 2,153, Illinois 1,863, California 1,480, Ohio 1,317, Michigan 1,241, and Massachusetts 1,053. All others examined less than 1,000. The smallest number (5) were examined in New

* This figure represents the number licensed by examination. It was not possible at this time to indicate whether these candidates were previously registered elsewhere but the figure is believed to be a fair estimate.

Mexico. The percentage of candidates who failed in the examinations in the last five years is given in the last column. The proportion of failures in all the states has increased from 62 per cent in 1929 to 66 per cent in 1933. In the five year period, 35.3 per cent of the applicants failed in Massachusetts and 26.7 per cent in Nevada, followed by New York with 15.3 per cent, Connecticut 12.2 per cent, and North Dakota 10.6 per cent. On the other hand, Kansas, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Carolina, South Dakota and Utah reported no failures while Arkansas, Georgia, Iowa, Louisiana, Michigan, Minnesota, Missouri, Tennessee, Texas and Vermont had less than 1 per cent of failures. A total

of 28,115 candidates were examined in the five years from 1929 to 1933 inclusive, of whom 26,247 passed and 1,868 failed. These figures represent examinations given and not individuals. A candidate who fails more than once in a given year has not been counted twice, but should he fail in one of the succeeding years he is counted in that year also. Likewise, if a candidate fails and later passes, whether in the same or a later

TABLE 5—*Internship Required by Medical Licensing Boards*

Oklahoma	1933	Wyoming	1931
Oregon	1933		

year, he is counted as passed and failed. With a total of 1,868 failures for the five year period, it seems likely that there were approximately 25,000 individuals examined. It is to be assumed that the majority of those who fail are later reexamined and licensed in some state. This figure, therefore, indicates a fair estimate of the number of physicians added to the profession each year. Table 4 gives exact totals on this point for the year 1933 and this study will be continued.

REGISTRATION 1904-1933

A study of totals and percentages (table 8) for each year beginning with 1904 is of interest. The number (5,658) examined in 1933 was 5 less than the number

examined in 1932 but 381 less than in 1904. By all methods, 7,180 were registered, 75 more than in 1932. It will be seen that there has been no constant increase or decrease in the total number of candidates registered from 1904 to 1933, although since 1906 the number licensed without examination has been increasing and those examined has diminished owing to the universal

of practice The medical practice act requires that the applicant be a graduate of a reputable school whose entrance requirements and course of instruction are as high as those adopted by the better class of medical schools and whose course of instruction embraces not less than four terms of eight months each

In Wisconsin there is one licensing board A license issued to osteopathic candidates authorizes them to practice osteopathy and surgery

In the District of Columbia one osteopath was granted the privilege to practice surgery by reciprocity

The 84 graduates of unapproved schools were licensed in nine states Alabama Michigan New Jersey, New Mexico, Tennessee and Washington each licensed one, and Arkansas licensed two In most of these states there was a specific reason for registration Illinois recognizes a medical school which is not in good standing with other state boards The Massachusetts law has already been described

These data are illustrated in chart 2 Those states which licensed more than ten such individuals are indicated in black and those licensing fewer than ten by slanted lines

Those individuals desiring to study medicine, who are unable to gain admission to schools either in the United States or in Europe, may endeavor to go elsewhere. The Council is attempting to make a study of medical education in South and Central America and a preliminary report was presented to the Annual Congress on Medical Education, Licensure and Hospitals

and Canada admitted to licensing examinations in this country. A similar tabulation is presented for the year 1933. One hundred and thirty-three schools are included and 8 of the licensing corporations of Great Britain, and 902 were examined during the five year period and 200 in 1933. The largest number examined represented the Regia Università di Napoli, 116, of whom 67.2 per cent failed, the Universität Wien in the five year period was second (61) and the Regia Università di Roma was third (41), while there were 37 from the University of Edinburgh. A study of the percentage failed is of interest.

In table 12 are assembled figures showing the standing during the five year period 1928-1932 of the graduates of medical faculties outside the United States

In twenty-nine states there is a requirement that the applicant must either be a naturalized citizen, have taken out first papers or declared intention of becoming a citizen, before a license to practice medicine will be granted. The states of Arkansas, Georgia, Kansas, Kentucky, Nebraska, Oklahoma, South Dakota, Tennessee and Wyoming require naturalization. Thirteen states require that first papers shall have been taken out, namely, Alabama, Florida, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, New Hampshire, North Dakota, Oregon, Virginia and Wisconsin. In Idaho, Indiana (reciprocal applicants only), Nevada, New Jersey, New York, Ohio and Rhode Island the applicant must have declared his intention of becoming a citizen before being eligible for registration.

BASIC SCIENCE BOARDS

Boards for the examination in the basic sciences of all those desiring to secure ultimately the right to practice the healing art functioned in seven states in 1933, namely, Arkansas, Connecticut, District of Columbia, Minnesota, Nebraska, Washington and Wisconsin. The states of Arizona and Oregon enacted basic science laws during the year, which became effective Jan 1,

1934 Statistics based on the number of candidates certified in 1933, and those who failed to secure this certification, together with totals for other years, are included in the accompanying tabulations. Similar data have been published in the State Board Number of THE JOURNAL since 1928.

The subjects in which examinations were conducted are listed in table 1.

As indicated in table 2, 658 candidates were examined by the seven boards in operation. Of this number,

TABLE 2—Applicants Examined—1933

Percentage Failed		11.0		35.0		81.8		100.0					15.3

598 were doctors of medicine and medical students (referred to hereafter as physicians), 43 osteopaths, 11 chiropractors and for 6 it was unable to determine what profession they represented. Of the physicians examined, 119 per cent failed, 350 per cent of the osteopaths failed and 81.8 per cent of the chiropractors, and all of those unclassified failed. There were 527 physicians who passed, 28 osteopaths and 2 chiropractors. Minnesota examined the largest number, 138, and also had the highest percentage of failures, 33.3 per cent, while Connecticut examined 133 and had only 4.5 per cent failures. The District of Columbia, on the other hand, examined only 43, of whom 32.6 per cent failed. Of osteopaths, Connecticut examined the highest number, 17, and Minnesota examined 12.

The number of certificates granted by examination, reciprocity and endorsement are listed in table 3. A total of 557 certificates were granted after examination, of whom 527 were physicians, 28 osteopaths and 2 chiropractors. There were 117 candidates certified without examination, by reciprocity or endorsement,

consisting of 108 physicians, 8 osteopaths and 1 chiropractor. Wisconsin accepted the greatest number without examination, 58 of whom were physicians, 7 osteopaths and 1 a chiropractor, while Minnesota registered 40 physicians and Nebraska, 10 physicians and 1 osteopath. Wisconsin registered seven of the eight osteopaths by endorsement.

Table 4 shows the number of candidates examined and certified from 1927 to 1933 inclusive. In 1933, 119 per cent of physicians failed, as compared with 50.0 per cent of nonmedical practitioners. In 1928, when five boards were functioning, there were 646 physicians examined, of whom 60, or 9.3 per cent, failed.

TABLE 3—Certificates Issued by Examination, Reciprocity and Endorsement—1933

	Examination					Reciprocity and Endorsement

and 59 nonmedical practitioners, of whom 28, 47.5 per cent, failed. In 1933, 635 physicians and 39 other practitioners were certified. During the seven year period a total of 4,239 physicians were examined, of whom 107 per cent failed and 470 other practitioners, of whom 51.3 per cent failed. During this period, 560 physicians were certified without examination, while only 26 other practitioners were so registered.

Altogether, 4,344 physicians and 255 others have been certified in the seven states. From the high per

TABLE 4—Total Candidates 1927-1933

centage of failures in the nonmedical group it seems apparent that the enforcement of basic science laws affects most seriously this group. Examination of the records of a considerable number of states having basic science laws will show that before such laws were enacted the number of nonmedical practitioners appearing for examination and licensure was very considerable and was growing.

The basic science board seems desirable in states having a multiplicity of examining and licensing boards. The object of these boards has been to provide a means

of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art

NATIONAL BOARD OF MEDICAL EXAMINERS

Statistics are herewith presented regarding the examinations and the issuance of certificates by the National Board of Medical Examiners. Similar material has been presented consecutively for sixteen

TABLE 1—Examinations in Part III

1928	1 430	1 101	211	118	9.7
1929	1 723	1 280	319	124	8.8
1930	2 043	1 540	322	175	10.2
1931	2 218	1 632	410	176	9.7
1932	2 341	1 849	355	137	9.9
1933	2 277	1 805	250	191	9.6
Totals	17 886	13 737	2 400	1 749	11.3

Four examinations were held in parts I and II during 1933, at which 1,234 and 714, respectively, were examined. In part I, 782 passed and 136, or 14.8 per cent, failed, and in part II, 651 passed and 63, or 8.8 per cent, failed. Since 1922 a total of 10,436 examinations have been given in part I and 5,312 in part II and up to Dec. 31, 1933, 6,707 individuals have been successful in passing part I and 4,712 in passing part II. The figure 10,436 includes over the twelve year period 2,536 who took incomplete examinations in part I and of the 5,312 who were examined in part II, 33 were incomplete. An incomplete examination is arranged for candidates taking part I at the end of their second medical year in schools whose third year curriculums include courses in one or two subjects of this part. The subjects thus postponed may be taken at any examination period after the candidate has completed them in his medical school. Also listed under this heading are those who wish to spend some additional time on one or two subjects. Incomplete examinations were not included when computing percentages since they represent neither a candidate eligible for certification nor a failure.

The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and

also some who pass parts I and II in the same year. Therefore they represent examinations conducted rather than individuals examined.

In the twelve year period there were 1,193 failures in part I, 15.1 per cent, and 567 in part II, 10.7 per cent.

The results of the examinations in part III since 1922 are presented in table 1. In 1933, 552 were examined, as compared with 549 in 1932. Of those examined, 4.5 per cent failed, while 5.1 per cent failed in 1932. During 1933, 527 were granted certificates. In 1922, 28 were examined, all of whom were granted certificates. During the twelve year period 3,621 were examined, of whom 3,446 were granted certificates and 174, or 4.8 per cent, failed. Here again a candidate having failed may subsequently receive a certificate. Since the National Board has functioned, 3,714 certificates have been granted.

The figures in table 2 represent the number of individuals examined during any one year. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1933 a student passed part I but later failed part II, he is listed as having failed. Taking this into consideration, there were 2,277 who took the examinations of the National Board during 1933, as compared with 2,341 in 1932. Only 525 were examined in 1922. A total of 13,737 individuals passed one or more of the examinations and 1,749, or 11.3 per cent, failed. Incomplete examinations have been taken by 2,400 individuals, many of whom have since received certificates.

Diplomates licensed on the basis of their credentials in the United States increased from 2 in 1917 to 391 in 1933, 2,190 having been so licensed since the National Board was created. A total of 3,714, however, have received the certificate of the National Board. In 1933, diplomates were registered as follows:

Number Registered		Number Registered	
Alabama	4	New Jersey	19
Arizona	3	New Mexico	1
California	9	New York	108
Colorado	2	North Carolina	3
Connecticut	29	North Dakota	1
Georgia	1	Ohio	7
Hawaii	6	Oregon	8
Idaho	2	Pennsylvania	15
Illinois	26	Puerto Rico	1
Iowa	1	Rhode Island	6
Kentucky	4	South Carolina	1
Maine	1	South Dakota	2
Maryland	5	Tennessee	1
Massachusetts	85	Utah	1
Minnesota	6	Vermont	2
Mississippi	1	Virginia	5
Missouri	9	Washington	8
Nebraska	1	West Virginia	1
New Hampshire	3	Wisconsin	3
Total			391

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of the following forty-two states and three territories:

Alabama	Iowa	Nevada	Puerto Rico
Arizona	Kansas	New Hampshire	Rhode Island
California	Kentucky	New Jersey	South Carolina
Canal Zone	Maine	New Mexico	South Dakota
Colorado	Maryland	New York	Tennessee
Connecticut	Massachusetts	North Carolina	Utah
Delaware	Minnesota	North Dakota	Vermont
Georgia	Mississippi	Ohio	Virginia
Hawaii	Missouri	Oklahoma	Washington
Idaho	Montana	Oregon	West Virginia
Illinois	Nebraska	Pennsylvania	Wisconsin
			Wyoming

Some of these states, however, have additional requirements.

A SPECIFIC METABOLIC FUNCTION OF THE THYROID

Many of the metabolic alterations of hypothyroidism have been well characterized by the results of investigations associating the clinical condition with changes in protein, water and salt metabolism. Although treatment of the disease with thyroid preparations results in a return toward the normal metabolic status, little is known concerning the precise nature of the variations produced in the intermediary processes of metabolism. Exact studies in these instances are of particular value, since a clear understanding of the chemical changes of body constituents may aid in the formulation of a picture of the mode of action of the thyroid hormone.

A carefully conducted study of this type by investigators in Berlin and Marburg¹ has made available a qualitative indication of the course of the altered metabolism in hypothyroid conditions and has followed the changes resulting during long treatment with thyroxine. The particularly striking feature of the urine obtained from hypothyroid patients was the high content of purine bases, this increase involved primarily adenine, an unoxidized purine present at most in minute quantities in ordinary human urine, but in these cases in amounts as great as sixty-four times the normal. The urine also contained the amino acid lysine in the naturally occurring isomeric form. The latter observation was interpreted as additional specific evidence of the inhibition of oxidation processes in hypothyroidism, since the excretion of this amino acid has been reported in other circumstances conditioned by impaired oxidation.² Treatment with thyroxine until a distinct clinical improvement was observed resulted in a gradual restoration of the normal urinary picture, the excretion of adenine rapidly decreasing to the usual level, the lysine disappeared from the urine under the influence of the hormone therapy.

As is well known the greater portion of purine bases is normally transformed by oxidation to uric acid. The

marked increased excretion of these purine compounds, particularly the unoxidized base adenine, together with the elimination of an unaltered amino acid, is interpreted as demonstrating the diminished oxidizing ability of the hypothyroid patients. It is the limitation of this function that apparently promotes alterations in the normal metabolic transformations of the purines, hence the investigators were led to consider their observations as an example of hormonal control of definite intermediary reactions of metabolism. However, it is perhaps somewhat early to assign solely to the thyroid gland the regulation of purine metabolism, in view of the fact that it may be possible to detect increases in unoxidized purines in the urine of individuals with a diminished metabolism resulting from some cause other than a hypofunctioning of this endocrine organ. Nevertheless, this suggested concept of the relationship between the thyroid and purine metabolism is of interest, other investigations of this type should produce further interesting information regarding the mode of action of thyroxine and other humoral agents.

A NEW METHOD OF PHYSIOLOGIC RESEARCH

At the beginning of one of the chapters of Claude Bernard's "Introduction to the Study of Experimental Medicine" he remarks

Only within very narrow boundaries can man observe the phenomena which surround him, most of them naturally escape his senses, and mere observation is not enough. To extend his knowledge, he has had to increase the power of his organs by means of special appliances, at the same time he has equipped himself with various instruments enabling him to penetrate inside of bodies, to dissociate them and to study their hidden parts. A necessary order may thus be established among the different processes of investigation or research, whether simple or complex: the first apply to those objects easiest to examine, for which our senses suffice, the second bring within our observation, by various means, objects and phenomena which would otherwise remain unknown to us forever, because in their natural state they are beyond our range. Investigation, now simple again equipped and perfected, is therefore destined to make us discover and note the more or less hidden phenomena which surround us.¹

In harmony with this conception of medical research the invention of new methods of investigation is one of the most likely aids to progress in the development of knowledge. Usually the expectation of the contributions from novel experimental technics should not be widely heralded until there is a modicum of real accomplishment to its credit. Now and then, however, the enthusiasm for a procedure of promise warrants modest mention. Thus, when physiologists succeeded in extirpating the liver without immediately fatal consequences it was soon evident that real contributions to the understanding of the hepatic functions were near at hand. Again, the ability to separate the thyroids from the parathyroid glands and the medulla from the

¹ Flossner O, Kutscher F and Wittneben W. Ztschr f physiol Chem 220 13 1933

¹ Bernard Claude. An Introduction to the Study of Experimental Medicine translated by H C Greene. New York. Macmillan Company 1927

cortex of the suprarenals, gave assurance that new discoveries in hormone physiology were likely to follow.

Somewhat comparable hope of advancement will be awakened by the new method of electrical excitation of the nervous system by remote control that has been developed in the research laboratories of physics at Harvard University and of the department of surgery at the Yale University School of Medicine by Light and Chaffee.² It takes one back to the days of laboratory experiments in the courses in physiology in which electrical stimulation of muscles and nerves was effected by the use of wire coils. Changes in the primary circuit, as in opening or closing it with a "key," induced electrical manifestation in the isolated secondary coil, which could readily be applied to exposed irritable tissues. In the procedure a small secondary coil, usually of 2,000 turns of copper wire, is actually implanted in an animal and one or both of its electrodes are taken to excitable centers. The wound is closed and after the animal recovers he can be placed within the magnetic field created by a specially designed primary circuit. The latter is entirely away from the experimental animal, but when the latter is placed within the range of the primary coil induction currents or "shocks" of the most varied character can be developed at selected localities in the body. Thus, as the investigators claim, the apparatus as designed removes the restrictions of time, anesthesia and restraint from experimental exploration of functions susceptible to electrical excitation. It provides a wide range of control of current, frequency and individual wave contour.

With this apparatus, which functions without moving parts, tests made thus far have produced typical Jacksonian attacks from stimulation of the motor area in the monkey, a condition of somnolence after stimulation of the hypothalamic region, contraction of the tongue from implantation of the electrode on the hypoglossal nerve, a copious flow of highly acid gastric juice, and violent peristalsis, from stimulation of the vagus on the lower esophagus. The implanted coils are covered with collodion, and some of these have now remained in place for as long as seven months without evidence of irritation of tissue or of cyst formation. What Light and Chaffee anticipate may be presented in their own words. It is hoped that this apparatus will make possible the study of functions which do not yield to stimulation of short periods but which may respond during experiments in which the excitation stimulates the character of that function and goes on, day and night, without disturbing in any way the habits or activity of the animal. It should be particularly useful in the study of the nervous control of autonomic functions such as sleep, sugar and water metabolism, menstruation, blood pressure normal and possibly abnormal digestive activity and temperature control.

CREATINURIA AND PHYSICAL FITNESS

The significance of creatinuria is a persistent problem in the story of metabolism. Although the urine of adult males on a creatine-free diet does not contain creatine, that substance is a constant and apparently normal component, along with the always present creatinine, in the urine of either sex up to the age of puberty. In women, of course, creatinuria is a physiologic occurrence, though only an intermittent one. During adult life in both sexes creatinuria may be induced, or increased, by a variety of experimental or pathologic conditions. It is quite usual in starvation. Lately creatinuria has been extensively studied in relation to certain types of muscular dystrophies.¹

Several years ago, when Powis and Rapier² discovered a diminished excretion of creatine during the night, they concluded that the chief explanatory factor appears to be the state of rest of the skeletal muscles associated with the temporary cessation of voluntary control that occurs during sleep. Other investigators have attempted to relate the creatinuria of childhood to the endocrine changes that result in puberty. A recent investigation by Light and Warren³ at the Lawrenceville School in New Jersey shows that among normal boys on an uncontrolled diet the percentage showing creatinuria remains fairly constant at ages from 14 to 17, drops perceptibly between 17 and 18, and was present in only one out of six boys between 18 and 19. The average creatine excretion for each yearly period declines with increasing age. Light and Warren were impressed by the wide latitude in years among adolescent males, during which creatine may be absent from a twenty-four hour urine specimen of an individual on a normal protein diet. What impressed them most during these studies was the frequent finding of the presence of creatine in one subject and its absence in another, both of whom were approximately the same age, weight and height on the same diet, and collecting the urine at the same time. The investigators were further impressed with the frequency of a certain lethargy and aversion to physical exercise among the subjects still excreting creatine.

In these studies, as Light and Warren point out, a close relationship between creatinuria and muscular activity in adolescent males is suggested by the definitely lowered creatine excretion among a group of boys on a high protein diet while resting in bed, as compared to the amounts excreted by the same subjects the following day, when attending to their usual school routine of study and exercise and on a normal protein diet. The marked increase in creatine excretion encoun-

tered on the first day of muscular activity following a period of confinement to bed due to an illness or injury, and its progressive decrease on each succeeding day, points to the fitness of skeletal muscles to meet the demands of exercise as an additional factor in the phenomenon of creatinuria among adolescent males

Current Comment

ARE MORE DOCTORS NEEDED?

The evils of overproduction in many fields have been vehemently discussed of late. The spotlight has been turned on surpluses of cotton and corn, but little has been said of the graver menace of excess production of physicians. The Commission on Medical Education in its final report a year ago pointed out that the ratio of doctors to population was increasing. Elsewhere in this issue of *THE JOURNAL*, the Council on Medical Education and Hospitals presents its annual compilation of the reports of the state boards of medical examiners. In 1933, 5,012 persons were added to the medical profession through licensure, the losses by death for the same period being approximately 3,500. The net gain, 1,500, is about one per cent of the number of physicians actually practicing in the United States. The census of 1930 shows an increase in population during the preceding decade of 6 per cent, or an annual rate of increase that is something less than six tenths of 1 per cent. Since all students of the question agree that the rate of increase is diminishing and that the country is tending toward a stable population, it is evident that the medical profession is increasing faster than the general population and that, unless the states promptly initiate measures to restrict the number of those licensed to practice medicine, a great surplus of unemployed doctors will become apparent. The social implications of such a condition would by comparison render the well known surfeit of agricultural products relatively innocuous.

CULTIVATION VACCINIA

Artificial cultivation of vaccine virus was first accomplished, about twenty years ago, by Steinhardt, Israeli and Lambert.¹ These investigators found that this filtrable agent multiplies (or is multiplied) in symbiosis with viable tissue fragments suspended in homologous plasma. Their simple cover glass technic was of main interest at the time in suggesting the possibility that this virus is perhaps not a fully autonomous vital unit. It suggested that it is possibly an enzyme-like or bacteriophage-like colloidal particle, capable only of symbiotic proliferation. This concept of filtrable viruses is one of the most plausible working hypotheses of the present time. Rivers and his co-workers² of the Rockefeller Institute afterward modified the Steinhardt

cover glass technic so as to make possible the cultivation of this virus on a large scale. In their final modification, an emulsion of minced chick embryo in Tyrode's solution is used as the culture medium. Rivers and Ward³ now report that, if transfers to fresh flasks of embryonic suspension are made at intervals of from four to five days, the virus can be cultivated indefinitely. A gradual reduction in antirabbit virulence, however, takes place, the two year old cultivation virus being practically avirulent for rabbits. At any time, however, a restoration of antirabbit virulence can be effected by testicular passage. The antihuman specificity of the cultivation virus, however, apparently suffers little or no qualitative deterioration. Thus far, 118 children have been vaccinated with cultivation vaccinia. Of these, 100 gave positive local pustular reactions. Eight of the hundred were afterward revaccinated with the routine board of health vaccine and found to be refractory. Two children in whom the cultivation virus did not take, however, were afterward successfully vaccinated with board of health calf lymph. The fact that the cultivation virus can be obtained free from bacterial contamination, can be used without the addition of chemical antiseptics, and causes only mild local reactions, with no fever or other objectionable systemic reactions, suggests extensive clinical study. Rivers' data, however, do not suggest its substitution for the more efficient routine calf lymph vaccine. It merely suggests its tentative use as a preliminary specific immunizing agent preparatory to routine vaccination with calf lymph.

MICRO-ORGANISMS, CAROTENE AND VITAMIN A

Investigations of vitamins seem to have established clearly that these essential dietary factors cannot be produced *de novo* by the animal organism. The fundamental thesis about the deficiency disorders now designated as avitaminoses is that the body is dependent on exogenous sources for certain organic substances without which it cannot function or develop properly. Sugar and fat can be synthesized readily in certain tissues—not, however, those vitamins with which we are at present familiar. Our complete dependence on food sources for these indispensable compounds has been questioned in view of the possibilities presented by the alimentary bacteria. They are always present in large numbers in the intestinal tract. They perish there readily, so that disintegration of the bacterial bodies can yield familiar nutrients for subsequent digestion and absorption by the host. Evidence is already at hand to show that, in some instances at least, alimentary bacteria correspond to plants in producing vitamin B. With respect to vitamin A the evidence has been negative. Recently, however, it has been demonstrated at the University of Wisconsin⁴ that certain micro

organisms can synthesize carotene, a recognized precursor of vitamin A in animal nutrition. Attempts by Baumann, Steenbock, Ingraham and Fred to effect the transformation of carotene into vitamin A by micro-organisms failed. Animals depleted of vitamin A were protected against avitaminosis by feeding dried cultures of the carotene-forming micro-organisms. The effect must have been due to the bacterial carotene. The Wisconsin investigators point out that, if the evidence is acceptable that carotene is actually synthesized by the organisms in question, in this respect these organisms resemble plants more closely than animals, since carotene when present in animals is of exogenous origin. The absence of vitamin A from micro-organisms and their failure to transform carotene into vitamin A likewise associate these organisms with plants, since vitamin A as such has not been demonstrated in a plant material. The similarity in structure of the carotene and the phytol molecules, as well as the fact that carotene always accompanies chlorophyll in plants, has led to the belief that carotene synthesis is in some way associated with chlorophyll activity. Micro-organisms, however, afford an illustration of the fact that the formation of carotene is not dependent on the presence of chlorophyll.

THE CLEVELAND SESSION

Medical Golfers to Play, June 11, in Eight Events

The twentieth annual tournament of the American Medical Golfing Association will be held at the Mayfield Country Club, Cleveland, Monday, June 11. Thirty-six holes will be played for the fifty prizes offered in eight events. This includes the championship event which has as its major prize the famous Will Walter Trophy, awarded since 1923 for low gross thirty-six holes. This trophy, designed by Edgar Millar and executed by the Cellini Shop, Evanston, Ill., symbolizes the evolution of medicine. The first handle depicts the age of primitive ignorance, with shaman witch doctor, spells and the invocation of nature gods to cure ailing mankind, from antiquity to 500 B. C. The second handle shows the age of Greek thinkers, bearing the serpents symbolic of Aesculapius, god of medicine—an age of thought and research, from 500 B. C. to 640 A. D. The third handle represents the age of medieval superstition from 640 A. D. to 1500 A. D., with an astrologer, the physician common to the dark ages. The fire of incantation rises behind the figure as he traces a cabalistic sign in the air. The fourth handle depicts the age of modern medical research, from the Renaissance to modern time with increasing light spreading from a figure symbolic of an enlarging vision. Winners since the cup was placed in competition have been Drs. E. A. Seaforth, San Francisco, 1923; George McKee, Pittsburgh, 1924; Homer Nicoll, Chicago, 1925; S. M. Hill, Dallas, Texas, 1926; George McKee again in 1927; Walter Sheldon, Rochester, Minn., 1928; John Loudon, Yakima, Wash., 1929 and 1930; George McKee 1931; S. M. Hill, 1932 and Mark Bach, Milwaukee 1933. Dr. Homer Nicoll is president. Drs. Charles Lukens, Toledo, and John W. Povers, Milwaukee, are vice presidents of the association which has a total membership of 1,110, representing every state in the Union. All male Fellows of the American Medical Association are eligible to membership. A cordial invitation is extended to every medical golfer to write the executive secretary, Bill Burns, 4421 Woodward Avenue, Detroit, for an application blank. An enjoyable day on June 11 will be the result.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15 Central daylight saving time (5 o'clock Eastern standard time, 3 o'clock Mountain standard time, 2 o'clock Pacific standard time).

The next three broadcasts will be as follows:

April 30 Science Saves Babies Morris Fishbein M.D.
May 7 Hospital Day W. W. Bauer M.D.
May 14 Pursuit of Longevity Morris Fishbein M.D.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central standard time. The next three broadcasts will be as follows:

May 3 Facts or Fallacies W. W. Bauer M.D.
May 10 Things Men Fear Morris Fishbein M.D.
May 17 Mischievous Misconceptions W. W. Bauer M.D.

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Thirtieth Annual Meeting held in Chicago Feb. 12 and 13, 1934
(Concluded from page 1308)

DR. G. M. WILLIAMSON, Grand Forks, N. D., in the Chair
JOINT SESSION OF THE COUNCIL ON MEDICAL
EDUCATION AND HOSPITALS AND
THE FEDERATION OF STATE MEDICAL
BOARDS OF THE
UNITED STATES

The Privilege of Reexamination in Professional Licensure

BERNARD C. GAVIT, J.D., Bloomington, Ind. The average of failures at bar examinations, including first timers and repeaters, for the United States for the year 1932 was 55 per cent. That result is rendered more painful by the further fact that ultimately in the neighborhood of 90 per cent of those who took the examinations for the first time will succeed at a subsequent examination in passing and being admitted to the bar. The medical profession is years ahead of the legal profession on the subject of licensure. The reasons are not hard to find. The medical profession has succeeded in eliminating to all practical purposes the commercial medical school. But last year there were 185 organized law schools in this country, and in the neighborhood of 55 per cent of those schools must be classified as commercial schools. They enroll about 55 per cent of the law students. At least ten new law schools were organized during 1933, all of them commercial, making no pretense of meeting any standards.

The medical profession has something more than a vocal belief in its place in society and the professional character of its members. A minimum of learning and character development is actually accepted as an essential point of departure. The bitter truth is that the legal profession is still given to talk. It is confused by the difficulty of actually choosing between its vocal standard which makes of the lawyer an aristocrat of learning and character, and the vicious American dogma of equality which makes every moron a potential lawyer. The problem of reexamination is very pertinent for the bar examination is the only mechanism at present that may possibly filter out some of the undesirables. It is obviously inadequate. The past results wherein some 90 per cent of all applicants regardless of their original preparation have succeeded in finally passing demonstrate that the minimum of a formal legal education required by the best of bar examinations is indeed a minimum for it can be acquired successfully by almost any one regardless of his scholastic and social background if he is persistent.

Medicine and law again part company for medical training and licensure include clinical experience. A very few states require a short clerkship for final admission to the bar, usually

only after the formal bar examination. Indeed, it seems that law schools will never be able to finance and conduct any extended clinical experience for law students on a parity with medical school training in their own hospitals, although a slight beginning has been made in a few schools. The practical difficulties seem insurmountable, and indeed the obvious solution seems to be a law office training following formal instruction supervised by the schools.

The best of bar examinations is an inadequate tool in solving the problem of admission to the bar. Any ex post facto determination of a candidate's fitness is unjust to the candidate, any strictly formal examination is unjust to the public and the bar. The commercial law school must go. But in the meantime we must struggle with the bar examinations and make them as effective as possible. The problem is immediate. The most effective immediate prophylactic is a limitation on the number of reexaminations permitted for each applicant. About one fourth of the states now have some such limitation, although the number of repeater examinations allowed is too high, being often as many as six or more. There is no good talking about law and medicine being professions unless one means that ideals of conduct forsake the immediate personal gain for a social value. A great many students are improved on by the sales talk of commercial schools. But the fact remains that one need not be too much concerned over those whose powers of perception are somewhat limited and who ultimately seem satisfied with a mediocre training. With good grace we can draw the line against the applicant who fails three times. A lawyer is in no position to give much advice to the physician on this subject. Medical standards for admission to examination for a license are so high that the problem of reexamination after failure is relatively unimportant. I suppose, however, that there are some who could still profitably be finally eliminated by the state medical examinations. There would seem to be no harm if medical reexaminations were limited to two. Certainly in the legal field it is a necessary expedient, for until the legal system turns to the elimination of the poorer grades of lawyer material through the standard schools some elimination must be effected through the state bar examinations. At present the elimination is negligible. Our final objective must be the elimination of the boards themselves through the imposition of the proper standards at the beginning rather than the end. The selection and training of professional men must ultimately be left to the schools, under proper supervision by an intelligent authority. In the meantime, tangible but indirect benefit can come by an early elimination of the repeater.

DISCUSSION

DR G M WILLIAMSON, Grand Forks, N D. Twenty-five years or more ago, state boards of examiners in medicine were having a similar experience as the state bar boards are having today. The commercial medical school is of the past and when the American Bar Association adopts a similar plan and organizes a council of the association to formulate and direct uniform courses of study, improvement will quickly follow. When state medical boards insisted that applicants for license must be graduates of an approved college and then that the college must be in class A, requiring at least two years in a college of liberal arts, commercial medical schools disappeared, in a similar manner, graduates of commercial law schools would find no place to go and the schools would cease to exist. State medical boards are bothered but little by repeaters. I attribute that to the uniform training medical students receive. When the American Bar Association adopts a plan similar to that which has worked satisfactorily for the medical profession, insisting on a high standard of preprofessional and professional training in approved colleges, repeaters will eliminate themselves. To a large extent the solution of this problem by the American Bar Association lies at the door of the state bar boards. If they would insist after a third failure that a candidate could not reappear at a fourth examination unless he produced evidence of a year's study in a college approved by the state bar board there would be fewer persons admitted to the bar and the quality of men practicing before the bar would be of a higher standard.

DR IRWIN D METZGER, Pittsburgh. In Pennsylvania we have almost come to the point where we say that the state

board examination is useless. We have been so careful in the examination of schools and hospitals, in their approval, as to satisfy us as members of the board that candidates, when they are admitted to the examination, should pass. If we approve the schools from which they were graduated, if we approve the hospitals in which they have had their clinical training should we not accept them as being qualified to practice medicine? We say, therefore, after the second examination, "You cannot take a subsequent examination unless you have had a year's work which shall be outlined by the board. It may be in a hospital, it may be in a medical school, but it must be specific. After you have had the additional year, you have another chance to take the examination and may repeat the second examination"—that means four of them, with one exception. We have what we call a practical examination in Pennsylvania, to which we admit candidates for various reasons who are not eligible for licensure by endorsement. If a person has been out of medical school for ten or more years, he is admitted to the practical examination. The main purpose is to catch exploiters that might have been traveling from place to place. In that examination, no second examination is given at all. Under the direction of the attorney general we are compelled to admit such applicant to a written examination for the second examination. Obviously, they seldom pass. Several have attempted to pass. The whole point is that it becomes in medicine a matter of assurance that these particular courses they have taken have actually "taken" with them, and that they have become trained adequately in medicine. The only excuse we have for examination in Pennsylvania is to see whether these people can apply practically what they have learned in the medical schools. Our questions are all based on that.

DR T J CROWE, Dallas, Texas. Two examinations are given in Texas if a candidate desires it; that is, the examination is bisected. We give what we call the technical subjects after the completion of the sophomore year in the medical college, while those subjects are fresh in mind. I believe that the state board should be a permanent organization and conduct examinations all the year round and give plenty of time to them. We had in our state an attempt on the part of the University of Texas to eliminate its graduates from the state board examination. They believe that a university supported by the state and passing on the qualifications of their graduates should be sufficient to entitle them to practice in the state.

DR C H EWING, Larned, Kan. In Kansas we permit no applicant to take the examination except that he be a graduate of a class A medical school. So why should we have these failures? We do not have them. It is a reflection on us if we do have failures. However, that does not apply to all of these boards, for they are compelled by the state laws to examine a different class of applicant.

DR FRANK M FULLER, Keokuk, Iowa. I suggest that we begin raising the standard of entrance rather than the standard of final examination. A good deal was said yesterday about the purpose of medical education. Some time ago I heard a definition of the purpose of education. The purpose of education is to train the mind and the will to do the thing that is to be done, at the time it should be done, whether you want to do it or not.

DR GILBERT FITZ PATRICK, Chicago. Did I understand the speaker to say that candidates in Iowa are examined by number? I would like to say that we ought to know more about the candidate. You are proposing to grant the man a franchise equal to his citizenship. I should like to see the biography of the man included in his application, so that I would know something about him.

DR FULLER. We have all that biography in Dr Biering's office, but in the examining board we are absolutely indifferent. We know that, if he has an application in, he is qualified to take the examination.

DR LANGLEY PORTER, San Francisco. If the state boards protect the communities from men who are incapable to practice they are doing their duty. They should not worry whether a man is a high grade student or a low grade student. That is the business of the medical schools.

BERNARD C GAVIT, J D, Bloomington, Ind I suppose it is obvious that the lawyers are at least twenty-five years behind the medical profession when it comes to the subject of licensure. Probably the best argument we have for any improvement is that that is a reasonably safe distance behind, even for a lawyer. There is one situation which, so far as a lawyer is concerned, is not humiliating. In Pennsylvania they have a system with their state board which I think approaches the ideal, and it is the only one in the country. They require the student to register with the state board when he starts his prelegal training, when he enters college, and they appoint a member of the bar, who supervises that man's prelegal education and his education through law school, so that when he comes up for examination they have a check on him, and if he should have been eliminated he is eliminated long before he gets into the law school.

Resumé of the History and Present Application of Medical Licensure in the United States

DR J N BAKER, Montgomery, Ala As one reviews the evolution of licensure as applied to the healing art, a spirit of altruism and what seemed best for the public weal largely dominate the picture. Orthodox medicine sponsored and furnished the leadership for the creation, in the various states, of machinery with which to measure all who assayed to treat diseases by any method whatever. Thus came into being in the states the medical licensing boards. Practically all of these laws more clearly defined the basic fact that the application of any mode of treatment to the human body must rest on at least an elementary knowledge of the structure of its component parts, as well as the changes that may take place as a result of disease. This attitude served to strengthen our position that the protection of the public interest is paramount and the sole justification for regulative laws, and also to show to lawmakers more clearly that any restrictive legislation on their part must be founded on the public weal. The second important service contributed by organized medicine was the effort put forth to right its own defects. In 1900 this country boasted 160 medical schools, some of which were more frankly commercial than scientific, with a few that were notoriously unsavory. Today it has but 77, in 1905 only 5 of the 160 exacted any premedical college training, whereas today every recognized medical school requires at least two years of college work and several demand a college degree for entrance to the study of medicine.

A questionnaire was sent to all licensing boards. On these returns, together with other available material, the succeeding comments on the present status of licensure are largely based.

Alabama is the only state having but one board passing on all applicants for the healing art. The personnel of the board is selected by organized medicine and is 100 per cent regular or orthodox. The legislature of Alabama in 1875 entrusted to the organized medical profession of the state the direction and control of both public health and medical licensure as well as the enforcement of its medical practice act. Thus far it has withstood all assaults.

At the beginning of this century there were in operation forty-one homeopathic and twenty-four eclectic schools, twelve of which were located in the state of Ohio alone. At present the list of the medical schools approved by the Council on Medical Education and Hospitals bears the names of but two such schools. Fifteen states make provision on their boards for one or both of these groups. Has not the time arrived for these boards to adjust minor internal differences and present to the public and to legislatures a solid and united front for orthodox medicine?

Osteopathy received its legal christening in Vermont in 1896 as a separate school of the healing art. The exaggerated importance attached by this school to vertebral displacement and nerve impingement seems to have caught the popular fancy and the grotesque mimicry of its manipulative therapy is seen to form the sole basis for numerous heterodox systems having no scientific leg on which to stand. These mixed boards represent compromise measures on the part of orthodox medicine. At present there are fifteen such mixed boards, most of which are meeting their problems in a harmonious manner.

There are eighteen states having separate boards for the various schools practicing the healing art. Here is the first

line of defense created by orthodox medicine for medical licensure battered down before the onrush of the followers of heterodox healing. It may be that an appreciation of the necessity for minimal scientific training, in states now having multiple boards, has led to the more recent experimental venture of basic science boards, the first of which were established in Wisconsin and Connecticut in 1925. There are now nine states operating under some plan whereby a "base line" of the fundamental sciences is set for all who propose to practice the healing art. Sufficient evidence has not yet accumulated to justify final conclusions regarding this newer venture. A final word concerning the National Board of Medical Examiners—the aristocrat of medical licensure and the fulfillment of the goal fixed by orthodox medicine for a single yardstick in the hands of one scientifically trained board. The fact that practically all states have given recognition to the diplomates of this national, unofficial board attests appreciation of the work being done within the ranks of organized medicine to elevate the standards of medical practice.

Within its own ranks, organized medicine must continue its purifying activities until complete unison is attained. This should not be difficult. As the standards are lifted, the unfit will fall by the wayside.

Reciprocal Agreements

DR JOHN R NEAL, Springfield, Ill Thirty-six of forty-four states that replied to the questionnaire practice some form of reciprocity. Florida does not reciprocate, because it is a tourist state and lies too near the center of population. Colorado, Connecticut, Idaho, Massachusetts, New Mexico, Rhode Island and Vermont are the other seven states that do not enter into reciprocal agreements. Colorado grants licenses on satisfactory credentials and by examination. Connecticut requires an examination of all applicants except diplomates of the National Board of Medical Examiners and physicians who have been in active and reputable practice in the United States for five years. Idaho does not enter into reciprocal agreements but judges each applicant on his merits. Massachusetts has no legal authority to enter into reciprocal agreements. New Mexico licenses by endorsement of credentials on the theory that reciprocity involves too many obligations. Rhode Island has not participated in reciprocity for two reasons: a lack of clear legal authority and lower standards for licensure in those states which by location would make of them the most convenient and logical to participate in reciprocity. Vermont does not like the reciprocity method of licensure. That state endorses the certificates of applicants from all states that have standards equal to her own. Among the thirty-six states that participate in reciprocity the practice is even less uniform.

Six states, Arkansas, Connecticut, Minnesota, Nebraska, Oregon and Wisconsin and the District of Columbia have a basic science law. Several other states, notably Texas, have laws that function in a way that achieves practically the same purpose. Arkansas requires the basic science examination of all graduates of medical schools who apply for reciprocal licensure. The other states modify this requirement in some cases. Minnesota, for example, accepts certificates of registration in basic science requirements.

An oral or written examination is not required of acceptable reciprocants in twenty-seven states.

Kansas and Nebraska charge applicants whatever fee the reciprocating state exacts from licentiates of their boards. The fee in other states ranges from \$20 to \$100.

The practice of medicine is a stable calling. The nature of medical practice discourages a shifting from state to state. Only the strongest motives can persuade the successful physician to give up his practice and begin again in a new locality. Daily the public learns more about the possibilities of the treatment and prevention of disease and becomes more exacting in its demands of skill and efficiency from the medical profession.

Illinois is one of the great population centers of the country. It attracts the migratory physician. Americans unqualified to enter medical schools in this country can acquire degrees in Europe and return to the United States with glowing credentials bearing the seal of illustrious institutions. Thirty-five states in this country have multiple examining boards that include respectively chiropractic, naturopathic, osteopathic, homeopathic

eclectic, basic science and others. Some states require a year's internship and some do not.

These are important things to consider in granting a license for the practice of medicine. It is felt that the qualified physician would welcome a test of his knowledge. For these reasons Illinois requires a clinical examination of all applicants for license. Candidates in convenient groups are taken to the ward, the surgical quarters, the eye, ear and nose infirmary, and the diagnostic laboratory of a general hospital. They are asked to diagnose the conditions and prescribe appropriate treatment of the patients and to recognize laboratory specimens. This procedure, it is felt, emphasizes, in the requirements for licensure, the interests of the public.

The ideal in reciprocal agreements would be uniformity. In the absence of that probability, each state must continue to set up its own requirements. The interests of the public demand an emphasis on the practical ability of the candidate rather than on the character of his credentials.

DISCUSSION ON MEDICAL LICENSURE AND RECIPROCITY

DR. P. E. BLACKBURN, Louisville, Ky. Dr. Baker reveals many reasons for any lack of conformity and coherence in our present licensure laws. I should like to add that there is a difference in point of view between the profession and the public, notwithstanding the legal construction of licensure purposes. The people think in terms of adequate and economical service while the profession, in the main, thinks of the scientific quality of service. On the one hand, the medical schools and organized medicine are crying for higher standards, and, on the other, the public too often decries the present high standards. Licensing boards furnish the battleground. There is no question that reciprocal relationships between states have had a beneficent influence. The Federation of State Medical Boards serves a fine purpose in keeping the medical profession unified in its ideals toward legitimate practice. As to the cults, although it is only the orthodox medical profession that can give scientific determination as to their value, we cannot deny the right of the public to give them a trial. Fortunately, their own limitations shorten their period of popularity. I am optimistic enough to believe that our legislators will continue to recognize that contributions to the relief of human suffering and the prolongation of life in the last century are products of medical science rather than the offspring of mysticism and cultism.

DR. HAROLD RAPINS, Albany, N. Y. Any one who had no knowledge of licensing boards in this country, after hearing Dr. Baker's paper, would certainly think that there was an infinite number of ways of attempting to do the same thing. When I started in this work I thought that the most desirable thing was to have a uniform type of licensing boards. I have changed my opinion. Apparently the different types of boards that have originated in different jurisdictions arose out of the needs of those jurisdictions. As a member of the National Board of Medical Examiners I am glad to see its influence spread, but I feel that it is not desirable, even if it were possible, to have national licensure. The public conception of what is the proper practice of medicine varies so much throughout the United States that I believe it is impossible to arrive at any common denominator except the very lowest one. I think that from a practical point of view the state is about the proper administrative unit for the carrying out of the medical practice acts. The point raised by Dr. Neal that there are three interests in the administration of the medical practice acts should be emphasized: the interests of the board, of the candidates, and of the public. The paramount interest must be that of the public. The state boards are legal bodies. They are appointed as part of a government, and their duty is primarily to the public of the state to see that only properly qualified practitioners may practice. A state board's sole duty is to pass on the ability of a candidate to practice. Certain individuals coming from one state to another suffer because the boards in the state where they were originally licensed also license students from inferior schools. It is wiser not to recognize a state board that examines from inferior schools such as in Massachusetts, even though an injustice may be worked on Harvard graduates. In the long run, the public would be better protected in that way. Dr. Neal raised an interesting question when he said it might be a good thing to use the transfer of a man from

one state to another as a time to reexamine him. That is a good idea, but I am not sure that it would be altogether just. When a man begins practice he should know something about the general body of medicine, but if he has been out ten years and has been doing good work in gynecology it is probably not reasonable to examine him in otolaryngology. This will, to a certain extent, I hope, be compensated for by the examinations now given by the specialty boards. I think it was President Jordan of Stanford, who was an eminent ichthyologist and was noted for the fact that he could recognize the name of any student on his campus. As he became more experienced he would forget a student's name. Finally he recognized only a few. Some one asked him why he no longer remembered the names of Stanford students. He said, "It is like this. I find that every time I remember a student's name I forget the name of a fish." I believe that every time a man really learns more about psychiatry or otolaryngology or gynecology or cardiology in the field in which he is concentrating, he is doing wisely to forget some of the things that he had to learn when he took his first licensing examination.

DR. FREDERICK ETHERINGTON, Kingston, Ont. We have had in Canada since 1912 the Canadian Medical Act, the chief function of which was to set up a board to conduct an examination that would qualify the candidate in any province of the dominion. Our experience has been wholly favorable, so that one by one the provinces are eliminating their own examinations and accepting that of the Canadian Medical Council. The practitioner takes the license and registers with the provincial council and is still under that council in matters of behavior. In that country the one examination for all practitioners is the one that is coming into vogue. I do not speak with any authority for the licensing boards, but I thought that our experience might be of benefit in the discussion.

DR. H. M. PLATTER, Columbus, Ohio. We seem to be passing at present through the period of trial and error. There are a great many things in each one of our administrations which ought to be eliminated. I believe that reciprocity in its essence is the practical application of the Golden Rule, the doing to others what we would have them do to us. I agree that the licensure of an older man by reciprocity is quite another thing. There is quite a percentage of physicians who go to sea after graduation, and if they are unfortunate enough to have to move to another state, perhaps it is well that the licensing boards should look them over. In addition to the practical examination there should be a searching questionnaire sent out concerning the applicant, particularly to his county medical society and to the medical members of the community in which he practiced. We should, through the Federation and the Council and the medical college association, get together to discuss the barriers that are interposed in the several states and attempt to get closer toward uniformity.

DR. W. SCOTT NAY, Underhill, Vt. Vermont endorses the certificates of all the states which have requirements and standards equal to our own, and that includes New York.

Medical Licensure in Latin America Preliminary Report

DR. WILLIAM D. CUTTER, Chicago. I am presenting this morning only briefly a preliminary study which is based largely on the laws of those countries and the legal requirements with regard to licensure. For the sake of convenience I have used the term "Latin America" to include those countries of North America and Central America, the West Indies and South America in which French, Spanish or Portuguese is the common language. In the Spanish and Portuguese speaking countries of America the right to practice medicine is based on the possession of a medical degree conferred by a legally recognized university. Generally the university degree 'physician and surgeon' has the same effect as a state license in this country. Any inquiry, therefore, into the requirements for medical practice in Latin America involves an analysis of the conditions under which the medical degree is obtained.

In the countries to the south of us there are forty-nine schools of medicine, distributed as follows: Mexico, 11, Cuba, 1, Haiti, 1, Dominican Republic, 1, Nicaragua, 2, Guatemala, 1.

Honduras, 1, El Salvador, 1, Brazil, 9, Argentina, 4, Chile, 3, Colombia, 3, Ecuador, 3, Bolivia, 2, Venezuela, 2, Dutch Guiana, 1, Paraguay, 1, Peru, 1, Uruguay, 1

It is impossible to formulate any generalization that holds literally true for each of the nineteen countries and forty-nine medical schools, but certain comments are generally applicable.

In the first place, the preliminary education necessary for matriculation in the faculty of medicine is almost universally the completion of the secondary school course, with or without the bachelor's degree. The "liceo" resembles the French secondary school, the "lycee." It may be accepted as extending beyond the four year high school of the United States. The courses, however, lean strongly toward the classical and humanistic studies, while the natural sciences receive decidedly less emphasis. Instruction is chiefly by lecture and demonstration. Laboratory facilities for individual experimentation are not generally found. Following the Spanish custom, large numbers of students enroll in the faculty of medicine merely as a means of securing a liberal education and a university degree without any thought of ever engaging in practice. It is possible that the character of the instruction is in some measure adjusted to the needs and capabilities of those students who lack a professional aim. Where classes are large, instruction is likely to utilize more extensively didactic methods. In consideration of the marked differences in the preliminary educational requirements and methods of instruction, it is suggested that the state medical boards composing the federation would do well to defer a definite evaluation of credentials from Latin American countries until more complete information is available.

DISCUSSION

DR FREDERIC W. SCHLUTZ, Chicago. The student body in the medical schools of Latin American universities are inordinately large in some of the universities. This is particularly true of Rio de Janeiro, Montevideo, Buenos Aires, Santiago and Lima. The student body divides into two groups, a comparatively small group, which is seriously seeking a medical education, and a much larger group, which uses medical education more as a medium to provide a cultural background. The sometimes enormous size of the student body influences the type of teaching that is offered. Practically without exception the Latin American university clinics have a wealth of fine clinical material. The hospitals are large, many of them exceeding 1,000 beds, and the outpatient departments are even larger, all of the material, almost without exception, being free cases. This vast amount of material cannot be adequately handled for thorough teaching. There are economic limitations and particularly limitations of lack of adequate staff. Teaching is almost precluded with these large groups and, it was my observation, almost nonexistent except to the small intimate group composed largely of the house officers. This throws the greater emphasis on didactic teaching, the amphitheater clinic and the outpatient teaching. This is exceptionally fine in most of the Latin American universities. It is the best of the medical teaching in Latin America, especially as exemplified in the French, Spanish and Italian schools. The medical libraries in some of the universities were far more complete in current journal material than they are in many North American universities. Their pathologic collections and the museums of pathology were excellent. Their laboratories, except possibly the laboratories in some of the universities in serology and in tropical medicine, were decidedly inferior to those of other countries. In comparison with the size of their hospital clinics, the staff and the house officers and assistants were surprisingly small. The junior men and house men who hold these positions have unequalled opportunities for fine clinical training but the numbers who are so fortunate as to secure these positions seem to be very small, and at the clinics that I visited were limited almost entirely to natives of their own countries. I had the impression that the attendance of foreign students at the universities is relatively small. The language difficulty is probably the chief factor. One needs to know Spanish, French or Italian. Unless the regulations for foreign medical men have changed in recent years it is not easy for the foreign practitioner to be registered in Latin American republics. A few years ago a four year residence period was required of the foreign student and then he had to take his examination for licensure in Spanish.

DR T. J. CROWE, Dallas, Texas. I am from a border state. We frequently have Spaniards coming to us for legalization, and we have great difficulty in determining their qualifications, for the reason that the Mexican government will not sign an affidavit in English. I believe that either the Federation of State Medical Boards or the Council on Medical Education and Hospitals should ascertain the standing of the colleges, not only of Mexico but of Central and South America, and symbolize them in some way in the handbook of rules and regulations of state boards, so that we who cannot speak Spanish will know which of those institutions are really worthy of consideration for examination. We take a foreigner only on examination. They have overnight revolutions in those countries, and the fellow who was at the head of the institution yesterday is exiled tomorrow and is in Texas looking for a license, when his crowd gets back in, maybe the next week, he goes back. We cannot tell anything about the individual half of the time.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Clinical Meeting—The tenth annual meeting of the Fort Smith Clinical Society was held, March 22, under the auspices of the staffs of St. Edward's Mercy, St. John's, and Sparks Memorial hospitals. The morning session was given over to clinics. The following physicians presented papers in the afternoon:

James H. Buckley. Recent Developments in the Newer Therapy of the Ear, Nose and Throat.
David W. Goldstein. Common Skin Diseases.
Arthur F. Hoge. Immediate Treatment of Extensive Burns.
Herbert Moulton. Relationship of Ophthalmology to the Practice of Medicine.
Arless A. Blair. Coronary Heart Disease and Angina Pectoris.
Curtis H. Kennedy. Evils of Present Day Prescription Writing and Dispensing.
Paul C. Schnoebele. St. Louis. Correlation of Clinical and X-Ray Findings in the Diagnosis of Gastrointestinal Lesions.
Leith H. Slocumb. St. Louis. Rectal Conditions. Diagnosis and Treatment.
Rutherford B. H. Gradwohl. St. Louis. Blood Development and Schilling Methods.

CALIFORNIA

Nutritional Survey—The San Francisco Health Department inaugurated a six weeks survey of the nutritional status of children whose families are on relief, March 1. Height and weight and an estimation of posture and muscle tone are included in a complete physical examination. Physical defects are recorded and efforts toward correction of these are made through the parents and school health authorities. A second survey will be made in about six months, in which it is hoped to determine whether there is an increase or decrease in the nutritional status in the population as measured by the health of children.

Society News—A clinical program made up the meeting of the San Francisco County Medical Society, April 10, with the following members of the staff of Stanford University School of Medicine, San Francisco, among others, as the speakers: Drs. Leo Eloesser, George D. Barnett, Karl L. Schaupp, L. Henry Garland and David A. Wood. Dr. Alfred Bichschowsky, director, University Eye Clinic, Breslau, Germany, gave a series of four lectures before the society, April 11-14. —Dr. William M. Gratiot, Monterey, addressed the Monterey County Medical Society, February 2, among others on 'Exfoliative Dermatitis'. —At a meeting of the Orange County Medical Society, February 6, Dr. W. M. Anderson, Los Angeles, spoke on 'Physical Diagnosis of the Heart'. —Among others, Dr. Albert G. Bower, Glendale, discussed 'Scarlet Fever and Its Treatment' before the Santa Barbara County Medical Society, February 12. —The Sonoma County Medical Society heard Drs. Harry E. Alderson and Charles Albert Shumate, San Francisco, discuss 'Skin Diseases and Their Treatment', February 8. —Dr. Harry Clare Shepardson, San Francisco, addressed the Stanislaus County Medical Society, January 12, on 'Treatment of Diabetes and Diabetic Coma'. —A paper on 'Pelvic Pain' was presented before the

Tulare County Medical Society, February 4, by Dr Robert Glenn Craig, San Francisco—Dr Jacob C Geiger, director, San Francisco County Health Department, was chosen president-elect of the Northern California Public Health Association at its annual meeting in Stockton, March 17, and Dr Ira O Church, Oakland, health officer of Alameda County, was elected secretary

COLORADO

Memorial Lecture—Dr Paul J Hanzlik, professor of pharmacology, Stanford University School of Medicine, San Francisco, gave the first annual Phi Rho Sigma Memorial Lecture at the University of Colorado School of Medicine April 16, on "Novel Antitoxic and Protective Action of Dyes." The lecture is sponsored by the local chapter of the fraternity in remembrance of deceased alumni

Society News—Dr Daniel R Higbee, Denver, spoke on "Relationship of Focal Infection to Pyelonephritis" before the Larimer County Medical Society, recently, in Berthoud—Speakers before a recent meeting of the Mesa County Medical Society in Grand Junction were Drs Donald M Maxwell and Frank J McDonough, Grand Junction, on "Use of Endocrines in the Treatment of Gynecological Conditions" and "Abdominal Diagnosis in Children," respectively—At a meeting of the Pueblo County Medical Society, recently, Dr Lester L Ward discussed digitalis

CONNECTICUT

Progress in Tuberculosis Survey—The number of roentgenograms taken in the school survey for tuberculosis cases in Connecticut between February 1 and 19 was 5,701, bringing the total to 44,131. The work has been completed in 116 towns and is under way in thirty-eight others leaving fifteen, or less than 10 per cent, of the 169 towns in the state that have not participated. The number of plates made represents slightly more than one third of the enrolment in the public schools, the bulletin of the state health department reports, and, since some of them were taken in parochial schools, the number would be a little less than one third of the total school population. When public funds were used for payment, a larger proportion of children had roentgenograms taken

DISTRICT OF COLUMBIA

Medical Bills in Congress—H R 9202, introduced by Representative Norton, New Jersey, proposes to authorize the commissioners of the District of Columbia to borrow from the Federal Emergency Administration of Public Works \$20,000,000 for the acquisition, purchase, construction and development of a tuberculosis hospital in the District of Columbia, for an extension of or an addition to the Gallinger Municipal Hospital, for a sewage and refuse-disposal plant and for other purposes. H R 9089, introduced by Representative Smith Virginia, proposes to confer police powers on the health officer of the District of Columbia, his deputy, assistants, agents and inspectors, including sanitary and food inspectors, milk and dairy inspectors and dairy farm inspectors

Group Hospitalization—The Medical Society of the District of Columbia has approved a plan for group hospitalization on the recommendation of its committee on medical economics. Through the Hospital Service Association, hospital care will be furnished up to and including twenty-one days for each contract year at a cost of \$9 for each subscriber. An enrolment fee of \$1 is also charged. If additional attention is required, the subscriber will be given a 25 per cent discount from regular hospital charges for similar accommodations. Under the contract, this care means bed and board, general nursing care, use of the operating room, surgical dressings, ordinary medication, routine laboratory examinations and other customary routine care, and obstetric cases after the contract has been in existence ten months. The benefits offered shall not include the services of the subscriber's attending physician or surgeon, roentgenologist, pathologist, physical therapist, anesthetist, special nurses, or their board. To be eligible for the plan, the subscriber must be under 65 years of age, in sound health, and must have been regularly employed for at least two months in an occupation approved by the Hospital Service Association. A hospital must be approved by the Medical Society of the District of Columbia, must not engage in the corporate practice of medicine and must bind itself to remain in this hospital group only while a member of the association. Any accumulated surplus will be used to reduce the cost to subscribers or to provide them with hospitalization over a longer period. Hospitals participating in the plan include Emergency, Garfield, Providence, Georgetown, Sibley, Columbia, Episcopal Eye Ear and Throat, George Washing-

ton and Homeopathic Casualty Hospital had endorsed the plan but, when this report was received, was unable to take action until the next meeting of its board

FLORIDA

State Medical Meeting at Jacksonville, April 30 May 2—The sixty-first annual meeting of the Florida Medical Association will be held at Jacksonville, April 30 May 2, with headquarters at the Mayflower Hotel, and under the presidency of Dr William M Rowlett, Tampa. Dr Howard A Kelly, emeritus professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, will speak Tuesday on "Readjustments in Surgery and Medicine." Other physicians participating in the program are

John S Helms Jr Tampa Surgical Management of Thyrotoxicosis
Julian E Gammon Jacksonville Arthritis
Matthew Jay Hipse Miami Treatment of Agranulocytosis with Yellow Bone Marrow
Arthur H Weiland Coral Gables Fractures of the Elbow
Gaston H Edwards Orlando A Perineorrhaphy
Kenneth A Morris, Jacksonville, Surgical Treatment of Pulmonary Tuberculosis
Bundy Allen and John R Boling Tampa Diagnosis and Surgical Management of Gastric and Duodenal Lesions
Orion O Feaster St Petersburg The Roentgenologist as a Consultant in Acute Abdominal Conditions
Joseph S Stewart Jr, Miami Intestinal Obstruction
Lloyd J Netto West Palm Beach Fibroid Tumors
William H Spiers Orlando Tuberculin in the Treatment of Arteriosclerosis
Louis Iverson Pensacola Recent Progress in Aviation Medicine
John S Tuberville Century Clinical Nature of Malignancies and the Principles of Treatment
Ralph N Greene Jacksonville Suggestions as to the Care of Brain Injury Cases
Paul Easton Jacksonville Action of Quinine on Malaria

Entertainment will include a golf tournament, luncheons, fishing, a smoker and the association dinner. Other societies convening during the annual session are the Florida Railway Surgeons Association, the Florida Society of Dermatology and Syphilology, and the woman's auxiliary of the state medical association

ILLINOIS

State Tuberculosis Meeting—The twenty-fifth annual meeting of the Illinois Tuberculosis Association will be held at the Hotel Emmerson, Mount Vernon, April 30-May 1. The tentative program is as follows

Dr Carl A Hedblom Chicago Thoracic Surgery with Special Reference to Thoracoplasty
Dr Henry C Swamy Chicago Pathological Aspects of Tuberculosis
Dr David O N Lindberg Decatur Use of Tuberculin and X Rays in Diagnosis of Early Tuberculosis
Dr Robinson Bosworth, Rockford Home Treatment of Tuberculosis
Dr Maxim Pollak Peoria Recent Developments in the Use of Artificial Pneumothorax

At the banquet, the speakers will include Drs Edward S Murphy, Dixon, Frank J Jirka, director, state department of health, Harold M Camp, Monmouth, and Henry Kennon Dunham, Cincinnati. Tuesday Child Health Day, will be given over to a specially arranged program on the health of children

Chicago

Hospital News—A gift of \$600 was recently given to the University of Chicago by Mr and Mrs Robert V Merrill to establish a memorial in honor of their son. According to the conditions, \$400 of the original \$600 shall be invested by the university, the income to be expended in behalf of children who are patients of the Bobs Roberts Hospital or clinic as gifts or loans, without interest, to their parents or guardians when they are unable to provide supplementary care

Society Disapproves of Radio Advertising—The exploitation of drugs, preparations and so called cures over the radio is viewed with disfavor by the Chicago Medical Society, according to a resolution unanimously adopted by the council, April 10. The symptoms and conditions for which these preparations are recommended frequently are indications of serious conditions calling for careful study by a qualified physician. It was further resolved that physicians request their patients to cooperate in sending protests to the Federal Radio Commission and to broadcasting stations against misleading and unwarranted radio medical advertising

Society News—The Chicago Urological Society was addressed, April 26, by Drs Herman L Kretschmer on "Resection of the Kidney," Frederick Lieberthal, "Perirenal and Pelvic Fibrolipomatosis and Its Relation to Replacement Lipomatosis," and Aloysius J Wochinski, "An Evaluation of the Serial Pyelography."—Dr Dallas B Phemister discussed "The Recovery of the Ancient Medical Manuscripts During the Late Middle Ages" before the Society of Medical History of Chicago, April 25. Dr Clarence A Earle presented "A Sketch of the

Life of Dr John A Kennicott,' and Dr James E Lebensohn, "1934—The Semicentenary of Local Anesthesia"—At the meeting of the Biological Photographic Association, April 24, Dr Max Thorek, among others, discussed "Photography in Medicine and Surgery"

IOWA

Society News—Dr Walter E Anthony, Ottumwa, will address the Wapello County Medical Society, May 8, on "Dyspnea as a Diagnostic Symptom" Dr Ralph J Selman Blakesburg, discussed "Early Frontier Medical Experiences" before the society, April 17 Drs Fred Moore and Dennis H Kelly, both of Des Moines, addressed the First Councilor District meeting in Charles City, April 3, on "Correlation of Child Health and the State Department of Health" and "Treatment of Infectious Diseases in Children," respectively

State Medical Meeting at Des Moines, May 9-11—The eighty third annual session of the Iowa State Medical Society will be held at Des Moines, May 9-11, with headquarters in the Hotel Fort Des Moines, and under the presidency of Dr Charles B Taylor, Ottumwa Guest speakers and their subjects are

Dr Roy Wesley Scott, Cleveland Syphilis as the Cause of Heart Disease
Dr Verne C Hunt Los Angeles Surgical Lesions of the Stomach and Duodenum
Dr John J Shea, Memphis Relationship of Otolaryngology to General Medicine
Dr Rosco G Leland Chicago Some Causes of Professional Unrest
The oration in medicine will be given by Dr George B Crow, Burlington, and the oration in surgery by Dr Edward M Myers, Boone Dr William E Ash, Council Bluffs, will be the toastmaster at the annual banquet, Thursday evening, when Dr Taylor will deliver the presidential address on "Who Are Graduates in Medicine?" Dr Gordon F Harkness, Davenport, president elect, will also speak on "Why Are We Here, and Where Are We Going?" Sectional conferences will occupy the program Wednesday and Thursday afternoons, with discussions on the various specialties Wednesday morning will be given over to a symposium on arthritis, in which participants will be Drs John C Parsons, Creston, John K. von Lackum, Cedar Rapids, Archibald F O'Donoghue, Sioux City, Charles W Ellyson, Waterloo, Addison C Page, Des Moines, and Oliver J Fay Des Moines Entertainment will include a formal reception, Wednesday evening, in honor of Dr Walter L Bierring, commissioner of health of Iowa, and President-Elect, American Medical Association The woman's auxiliary of the society will convene in its fifth annual meeting, May 9, and the State Society of Iowa Medical Women will hold its thirty seventh annual meeting, May 8

KANSAS

State Medical Meeting at Wichita, May 9-11—The seventy sixth annual meeting of the Kansas Medical Society will be held at Wichita, May 9-11, under the presidency of Dr William F Bowen Sessions will be held at the Allis and Lassen hotels The tentative program includes the following physicians, who will discuss the topics named, among others

Edgar V Allen Rochester Minn, Hypertension
Louis A Brunsting Rochester Minn Recent Advances in Eczema
Cyril M MacBryde St Louis Anterior Hypophysis
Paul B Magnuson, Chicago Arthritis with Injuries Superimposed
Thomas A Brown St Louis Puerperal Infections
Harry S Gradle, Chicago Eye Injuries and Their Immediate Treatment
Oscar W Bethea New Orleans Specific Treatment of Asthma
Edwin C Ernst St Louis A Rays
Alfred I Folsom Dallas Prostatic Resection
Karl A Meyer Chicago Present Status of Gastric Surgery
Lee W Dean St Louis Functional Ear Test for Hearing
Louis Rudolph Chicago Vertex Dystocia
John L Jelks Memphis Rectocolonic Disease

MARYLAND

The Thayer Memorial Wards—February 24 marked the official opening of the Thayer Memorial Wards in the Hurd Memorial Hall of Johns Hopkins Hospital Judge Henry D Harland president, board of trustees, Johns Hopkins Hospital presided and speakers included Dr Simon Flexner director, Rockefeller Institute for Medical Research on Dr Thayer Physician, Scientist, Cosmopolitan Joseph S Ames PhD president of Johns Hopkins University, Dr Thayer as a Teacher," and Dr John M T Finney emeritus professor of surgery Johns Hopkins University School of Medicine Dr Thayer as a Man' The Thayer wards are two old wards remodeled to form cubicle rooms There are twenty-two cubicles on each floor one for women one for men The cost of alterations was about \$30,000 A large part of this sum was contributed by friends of Dr Thayer

MASSACHUSETTS

Another Physicians' Art Society—The newly organized Physicians' Art Society opened an art exhibit in the Boston Medical Library, April 23, which will continue until May 5 The total number of exhibits in all fields of art is 129, the work of the following physicians and dentists

Dr William Lloyd Aycock Boston	Dr Lewis M Hurxthal Brookline
Dr Edward P Bagg Jr Holyoke	Dr Percy E Ireland Boston
Lawrence W Baker DMD Boston	Dr Frederick C Irving Brookline
Dr James Dellinger Barney Boston	Dr James C Janney Cambridge
Dr Richard J R Caines Winthrop	Dr Ralph C Larrabee Boston
Dr Walter B Cannon Cambridge	Dr James Howard Means Boston
Dr William B Castle Boston	Dr Harris P Mosher Boston
Dr Frederic J Cotton Boston	Dr Albert A Pastene Norton
Dr William P Coues Brookline	Dr Claude D Payzant West Medford
Dr Harold W Dana Brookline	Dr H Hale Powers Brookline
Dr Cecil K Drinker Brookline	Dr Eli C Romberg Boston
Dr Maurice A Gilbert Chelsea	Dr Walter F Sawyer Fitchburg
Dr William W Harvey Boston	Dr Somers H Sturgis Boston
Dr S Hertz Boston	Dr Fritz B Talbot, Brookline
Dr Lewis W Hill Boston	Dr Grantley W Taylor Brookline
	Dr Sidney C Wiggan Newton

The Physicians' Art Society was organized in Boston in February to foster arts and crafts among members of the medical and allied professions, and to hold annual exhibits of the work of its members Dr James Dellinger Barney is president and James F Ballard, director of the Boston Medical Library, secretary Membership is open to all members of the Massachusetts Medical Society, Massachusetts Homeopathic Medical Society, Massachusetts Dental Society, and allied dental societies, and other related organizations, and also hospital interns and medical students

MINNESOTA

Dr Bierring Gives Jackson Lecture—Dr Walter L Bierring, President-Elect, American Medical Association and state health commissioner of Iowa, gave the first annual lecture under the Clarence Martin Jackson Lectureship at the University of Minnesota Medical School, Minneapolis, February 27 He discussed "Historical Sequence of Medical Events" The lectureship was established by Phi Beta Pi in honor of Dr Jackson, who is head of the department of anatomy at the medical school

County Society Extension Course—The newly organized Renville County Medical Society inaugurated a university extension course, April 10, with Dr Emil C Robitschek speaking on 'Colles Fracture' The second in the series was given April 17, with Dr E A Loomis as the speaker on "Refraction, with General Practitioner's Equipment", the third, April 24 with Dr Edgar T Herrmann, anaphylaxis Subsequent speakers and their subjects are

May 1	Dr Frederick H K Schaaf	Bedside Diagnosis
May 8	Dr Hewitt B Hannah	Neuritis
May 15	Dr William H Condit	Gynecology Office Practice
May 22	Dr Thurston W Weum	Technic of Labor
May 29	Dr Frederick C Rodda	Abnormal Child Examination and Diagnosis

MISSISSIPPI

State Medical Meeting in Natchez, May 8-10—The Mississippi State Medical Association will convene in annual session in Natchez, May 8-10, with headquarters at the Eola Hotel, and under the presidency of Dr John W D Dicks Natchez Dr John M T Finney, Baltimore, will deliver the annual oration Tuesday evening Out-of-state speakers will include Drs H Earle Conwell Fairfield Ala, on "Problems Frequently Encountered in the Treatment of Fractures", Kosciusko W Constantine, Birmingham Ala, 'Glaucoma', Waller S Leathers, Nashville, Tenn, An Analysis of the Hookworm Problem in Mississippi" and James S McLester Birmingham The Physician of Yesterday and Today" Other speakers will include

Dr Paul B Brumby	Lexington Role of Glucose in Surgery
Dr Leslie V Rusch	Meridian Present Status of Surgery in Gall bladder Disease
Dr Robert H Brumfield	McComb Stricture of Ureter
Dr Thomas F Welford	Columbus Retrocecal Appendixes
Dr De Witt Hamrick	Corinth Dietary and Glandular Deficiencies in Eye Ear Nose and Throat
Dr Guy C Jarratt	Vicksburg Congenital Syphilis
Dr George W F Rembert	Jackson Allergic Phenomena
Dr Henry Bo well	Sanatorium The General Practitioner and Tuberculosis
Dr William Krau	Meridian Principles Underlying the Treatment of Malaria

Mayor S B Laub Natchez will give an address of welcome on behalf of the city of Natchez and Dr James C Rice Natchez on behalf of the Homochitto Valley Medical Society

NEBRASKA

Society News—At a meeting of the Southwestern Nebraska Medical Society, McCook, March 8, speakers were Drs David L Morse, Hayes Center, on "The Tonsil Problem", John N Stewart, Stratton, "Measuring Impalpable Objects with X-Rays" and George W Hoffmeister, Imperial, "Recent Literature on Causes of Prostatic Hypertrophy"—Dr Geza de Takats, Chicago, will address the Omaha-Douglas County Medical Society, Omaha, May 15, on "Diagnosis and Treatment of Peripheral Vascular Disease"

NEW JERSEY

Bill Passed—A 373 has passed the assembly, proposing to appropriate \$10,000 to the state department of health for the purchase of diphtheria toxoid and/or toxin-antitoxin and smallpox vaccine, which is to be distributed free by the department in accordance with its rules and regulations

Paging Mr Rando—Arthur Joseph Rando who has served as intern and resident physician at several New Jersey hospitals, has obtained these positions by a false claim that he is a graduate of Tulane University of Louisiana New Orleans, recent investigation revealed. Officials of Tulane state that Rando is not known there. A further claim that he had been employed at Charity Hospital, New Orleans, was not substantiated by the hospital. Records of the American Medical Association do not show that any physician by this name was ever graduated from any medical school, obtained a license to practice or has ever been enrolled in any medical college. When visited by investigators for the New Jersey state board of medical examiners, Rando made an appointment to see them later, but when the investigators called at his home several days later, they were informed that he had departed.

NEW YORK

Bills Passed—The following bills have passed the assembly and the senate. A 415, to amend the pharmacy practice act by proposing, among other things, (1) to define a pharmacy as "any place registered by the board in which drugs, chemicals, medicines, prescriptions or poisons are possessed for the purpose of compounding, dispensing or retailing or in which drugs, chemicals, medicines, prescriptions or poisons are compounded, dispensed or retailed or in which such drugs, chemicals, medicines prescriptions or poisons are by advertising or otherwise offered for sale at retail," and (2) to provide that every pharmacy shall be under the personal management of a duly licensed and registered pharmacist, A 485, to amend the workmen's compensation act by proposing to make dermatitis venenata compensable when acquired in "any process involving the use of or direct contact with acids, alkalis or oil, or with brick cement, lime concrete or mortar capable of causing dermatitis (venenata)", and S 1677, to amend the education law relative to credentials by proposing to make it unlawful for any person to attempt to obtain by fraudulent means any certificate of registration or any diploma, certificate or other instrument, or duplicate thereof, purporting to confer any literary, scientific professional or other degree. The following bills have passed the assembly. A 1567 to amend the law prohibiting the admittance of unvaccinated children to schools in cities of 50,000 or more inhabitants by proposing that an unvaccinated child shall be admitted to school on the recommendation of the city board of health or such other board, commission or officers of such city having jurisdiction of the enforcement of the law, A 2118 to amend those provisions of the medical practice act relating to osteopathy by proposing to extend to a considerable degree the scope of a license to practice osteopathy. S 1375 has passed the Senate proposing to amend the law relating to registered nurses by requiring applicants for such registration to be citizens of the United States.

New York City

Seventh Harvey Lecture—Dr Thomas M Rivers of the Rockefeller Institute for Medical Research delivered the seventh lecture of the Harvey Society at the New York Academy of Medicine, April 19. His subject was "Filterable Viruses, with Particular Reference to Psittacosis"

Hospital Advisory Board—Dr Sigismund S Goldwater, commissioner of hospitals, has appointed the following board of administrative consultants: Drs Willard Cole Rappleye, Jacob J Golub, Willis G Nealley, John H Wyckoff, Jr, George Baehr, Ernst P Boas and Haven Emerson and Clarence E Ford assistant commissioner, state social welfare department.

Hospital News—Dr Richard H Jaffe, Chicago, delivered a lecture at Mount Sinai Hospital April 6 on "Modern Concepts of the Pathogenesis of Progressive Pulmonary Tuberculosis". Dr Richard Bauer, Vienna, gave a lecture on "A New

Treatment for Various Types of Coma," March 1, at Mount Sinai Hospital—Louis I Dublin, Ph.D., delivered an address at the annual meeting of the directors of the Hospital for Joint Diseases, April 4, on "The Hospital, the Doctor and the Community."

Afternoon Lectures at the Academy—Recent Friday afternoon lectures at the New York Academy of Medicine have been delivered by the following speakers, among others:

- Dr Robert T Frank, The Endocrine Glands and Their Relation to the Diagnosis and Treatment of Obstetrical and Gynecological Conditions
- Dr Samuel J Kopetzky, Significance and Treatment of Paranasal Sinus Infections in Infants and Adults
- Dr Alexander Randall, Philadelphia, The Story of Renal Tuberculosis
- Dr Louis C Schroeder, Disorders of Adolescence from the Standpoint of the Pediatrician

Society News—Dr Leopold Jaches addressed the New York Roentgen Society, March 19, on "Bone Changes in Cases of Disturbance of Lipoid Metabolism"—A symposium on acute and chronic empyema was presented before the New York Surgical Society, March 14, by Drs John F Connors, Harold Neuhoof, Adrian V S Lambert and Walton Martin—Drs Charles Gordon Heyd and Charles Hendee Smith addressed the Medical Society of the County of Queens, March 27, on "Hyperthyroidism in Children and "Pneumonia in Children," respectively—Dr George W Crile, Cleveland, addressed a joint meeting of the Queensboro Surgical Society and the Brooklyn Surgical Society, April 11, on "Pathologic Physiology of the Sympathetic Nervous System and Its Treatment by Adrenal Denervation"—Dr Joseph C Beck, Chicago, was guest speaker at a joint meeting of the Medical Society of the Greater City of New York and the Society of Plastic and Reconstructive Surgery, April 13, on "Plastic Repair of Defects Following Radical Surgery for Malignancies About the Head and Neck."

NORTH CAROLINA

Society News—Dr George E Williams, Valdese, addressed the Catawba Valley Medical Society, Lincolnton, March 13 on "The Value of Psychiatry in the Practice of Medicine"—Dr Michael A Burns, Philadelphia, addressed the Guilford County Medical Society, High Point, March 2, on treatment of neuroses—Drs Donnell B Cobb, Goldsboro, and John A Winstead, Rocky Mount, addressed the fourth district medical society at a meeting in Smithfield, February 27, on diagnosis of diseases peculiar to women and amebic dysentery in infants, respectively—Dr Springl Weizenblatt addressed the Buncombe County Medical Society, Asheville, March 5 on tuberculous disease of the eyes—Drs Alva B Craddock, Paul H Ringer and Julian A Moore, Asheville, addressed the Mecklenburg County Medical Society, Charlotte on diagnosis and treatment of tuberculosis—At a meeting of the Durham Orange County Medical Society, at Duke University School of Medicine, Durham, March 9, speakers were Drs Oscar L Miller, Charlotte, on "Fractures of Both Bones of the Fore arm" and Luther Emmett Holt Jr, Baltimore, on "Absorption and Utilization of Fat"

OREGON

Society News—The Southern Oregon Medical Society will hold its annual meeting at Medford, May 8. Among the speakers will be Dr George W Swift, Seattle, on "Traumatic Diseases of the Brain"—Drs Raymond E Watkins and Frank R Menne, Portland, addressed the Central Willamette Medical Society, Corvallis, March 1, on "Carcinoma of the Female Genital Organs"—Dr J B Gillis, Jacksonville, addressed the Jackson County Medical Society, Ashland, March 7, on focal infection—Dr Gilson A Ross, Eugene, presented a paper before the Lane County Medical Society, Eugene, March 15, on treatment of fractures of the neck of the femur—At a joint meeting of the medical societies of Union, Wallowa and Umatilla counties at Hot Lake Sanatorium, March 9 Dr Lyle B Kingery, Portland, gave an address on skin diseases.

State Society Rejects Fee Schedule for Medical Relief—The council of the Oregon State Medical Society at a meeting in Portland April 4, adopted a resolution approving the action of its medical advisory committee in refusing to accept a fee schedule offered by the state relief committee. The relief committee had previously rejected a fee schedule drawn up by the society's representatives. In explanation of this action the resolution states that the fee schedule proposed was unreasonably low, not based on cost of the service to be rendered, but purely arbitrary. It is set out that a craft or profession is qualified to determine what is a reasonable and acceptable price for its services. The council took the position that "we will continue to care for our patients as we

always have whether they have means to pay us or not
We are carrying a load that belongs to the whole public,
not to us alone."

PENNSYLVANIA

Personal—Dr Howard K Petry, clinical director, Torrance State Hospital, has been appointed superintendent of the Harrisburg State Hospital, to succeed Dr Edward M Green, who recently resigned after serving sixteen years—Dr Arthur E Davis has been appointed director of public health of Scranton

Society News—Dr Willard H Kinney, Philadelphia, addressed the Cambria County Medical Society, Johnstown, April 12, on "Hematuria—Its Significance and Management" and Dr Louis H Mayer Jr, Johnstown, explained the technic of examination for the emergency relief program—Speakers at a meeting of the Allegheny County Medical Society, Pittsburgh, April 17, were Drs Ehrhardt Ruedemann, on "The Ear in General Medical Diagnosis", J Watson Harmeier, "Headache," and Josiah R Eisaman Jr, "Abdominal Pregnancy"—Dr George J Feldstein addressed the Pittsburgh Pediatric Society, April 20, on vaccine therapy of whooping cough

Philadelphia

Society News—Dr Frank H Lahey, Boston, addressed the Philadelphia County Medical Society, March 28, on "Diagnosis and Management of Hyperthyroidism and Associated States"—Mary J Hogue, Ph D, among others, addressed the Physiological Society of Philadelphia, March 19, on "The Effect of Amebicidal Drugs on Tissue Culture Cells"—Dr William Drayton Jr and George E Coghill, Ph D, addressed the Philadelphia Neurological Society, March 23, on "Pneumocranium in Treatment of Traumatic Headache, Dizziness and Character Change" and "Growth of Spinal Cord in Relation to Reflex Action," respectively—At a joint meeting of the Philadelphia Psychiatric Society and the section on medical history of the College of Physicians of Philadelphia, April 13, Dr Theodore Diller, Pittsburgh spoke on "Human Credulity as Illustrated by Belief in Witchcraft"

Symposium on Amebic Dysentery—Members of the faculty of the Woman's Medical College of Philadelphia presented the program of the Philadelphia County Medical Society, April 11 Drs John Stewart Rodman and Henry D Jump and Helen Ingleby discussed the surgical complications, pathology and prophylaxis and treatment of amebic dysentery—Dr Chevalier Jackson spoke on "Prophylaxis of Bronchiectasis" and Dr Winifred Bayard Stewart on "Encephalitis in Children, Apparently Congenital and Due to Maternal Influenza" A special meeting was held, April 13, for senior medical students of Philadelphia in the interest of promoting the periodic health examination Speakers were Drs Thomas A Shallow, on "The Relation of the Doctor to the Public and the Commonwealth", Moses Behrend, "Value of Medical Organization" and Francis F Borzell, "Medicine and Economics"

SOUTH CAROLINA

State Medical Meeting at Charleston—The eighty-sixth annual session of the South Carolina Medical Association will be held at Charleston May 1-3, under the presidency of Dr Robert E Abell, Chester Guest speakers will be

Dr Fred W Rankin Lexington Ky Diagnosis and Surgical Treatment of Malignant Lesions of the Large Bowel
Dr James R McCord Atlanta Ga Conservative Treatment of Eclampsia
Dr Roscoe G Leland Chicago Trends in Medical Economics
Dr Jack C Norris Atlanta Cardiovascular Renal Disease

Among South Carolina physicians who will present papers are

Dr Walter R Mead Florence Intracranial Hemorrhage Without Paralysis
Dr Lawson Paul Barnes Bennettsville Importance and Ease of Prescribing Diets
Dr Joseph Decherd Guess Greenville Hemolytic Anemia of Pregnancy
Dr Julian P Price Florence Use and Abuse of Drugs in Treating Children
Dr Charles Williams Bailey Spartanburg Anemia in Infants and Young Children
Dr Marion H Wyman Columbia Resistance to Infection by Fixed Tissue Cells

The South Carolina Public Health Association will hold its annual meeting Tuesday morning May 1 speakers will be Drs John A Ferrell New York president American Public Health Association L L Williams and Calvin C Applewhite of the U S Public Health Service on malaria and community sanitation, respectively and William A Mulherin Augusta Ga on preventive pediatrics The president's reception and ball will be held Wednesday evening at the Francis Marion Hotel

VIRGINIA

Personal—Dr George B Arnold has been appointed superintendent of the State Colony for Epileptics and Feeble-minded Colony, to succeed Dr John H Bell—Dr Hugh C Henry, Petersburg has been appointed a member of the state advisory board on mental hygiene

County Societies Organized—Six counties included in the Medical Society of Northern Virginia recently formed medical societies with provisional presidents to serve until the meeting of the district society, as follows Clarke County, Dr Charles O Dearthmont, White Post Warren County, Dr David M Kipps, Front Royal, Shenandoah County, Dr William C Ford, Woodstock, Frederick County, Dr Hunter H McGuire, Winchester, Rappahannock County, Dr James G Brown, Woodville, and Page County, Dr George R H Long, Luray

WASHINGTON

Society News—Drs Milo T Harris, Port Arthur, Texas and Samuel E Light addressed the Pierce County Medical Society, Tacoma, recently, on "Roentgenologic Diagnosis of Diaphragmatic Hernia" and "Relation of Dermatology to General Medicine," respectively—Drs Laurence Selling Portland, Ore, and Charles M Doland, Spokane, addressed the Spokane County Medical Society, Spokane, February 8 on "Acute Encephalomyelitis" and "Abdominal Injury Without External Evidence of Trauma," respectively

GENERAL

Change in Status of Licensure—The California State Board of Medical Examiners reports the following

Dr John P Sandboldt Monterey found guilty on two charges of violation of the federal narcotic law placed on probation for five years during which time he must not apply for or have a federal narcotic permit nor have narcotics in his possession The periods of probation on the two charges are to run concurrently

Dr Peder S Bruguere San Francisco license restored February 26 placed on probation for two years

Dr Schuyler A Barber Porterville license restored February 26 placed on probation for five years without narcotic possession or privileges

National Tuberculosis Association—The thirtieth annual session of the National Tuberculosis Association will be held in Cincinnati, May 14-17, with headquarters at the Netherland Plaza Hotel At the opening general meeting Monday evening, Dr Stuart Pritchard, Battle Creek, Mich, will give his presidential address and Dr Marion Dorset, Washington D C, will give an address on "The Role of Tuberculin in Tuberculosis Control" Ralph W G Wyckoff Ph D New York will show a motion picture on growth of acid fast bacilli and the Trudeau medal will be awarded Among speakers listed on the tentative program are

Dr Alphonse R Dochez New York Acute Infections of the Upper Respiratory Tract

Drs George R Duncan and Ernest S Mariette Oak Terrace Minn Hyperpyrexia in the Treatment of Tuberculosis

Drs Alfred H Caulfield and George C Anglin Toronto Ont Futurity Handicap of the Tuberculosis Contact

Dr Isadore D Bronfin Denver Amyloid Degeneration of the Suprarenal Glands as a Factor in Producing Symptoms of Addison's Disease in Chronic Pulmonary Tuberculosis

Dr Donald E Vochem Newark Ohio The Problem of Anemia in Clinical Tuberculosis

A symposium on collapse therapy will be presented by Drs Ronald V Christie, Montreal, Que, Edgar M Medlar, Mount McGregor, N Y Lawrason Brown, Saranac Lake, N Y and Carl A Hedblom Chicago The American Sanatorium Association will hold its annual session Monday, May 14

Medical Bills in Congress—Senator Copeland, April 20 announced in the Senate his intention next week, or very soon thereafter, to call up for consideration S 2800 the Copeland food drugs and cosmetics bill *Changes in Status* H R 3768 has passed the House changing the name of the retail liquor dealers stamp tax in the case of retail drug stores or pharmacies to medicinal spirits stamp tax S 2794 to amend the longshoremen's and harbor workers compensation act has been reported to the Senate with amendments (S Rept 588) Among other things, the bill would authorize a deputy commissioner to suspend payment of compensation if the injured employee unreasonably refuses to submit to medical and surgical treatment The companion bill in the House H R 8057 has been reported to the House, with amendments (H Rept 1244) *Bills Introduced* S 3382 introduced (by request) by Senator Thomas Oklahoma provides that Osage Indians who are habitual drunkards or habitual users of narcotics may be committed to institutions H R 9121 introduced by Representative Brunner New York and H R 8977 introduced by Representative Rudd New York propose to amend the Radio Act of 1927 as amended

so as to require all radio broadcasting stations to allocate not less than one fourth of their operating time to educational, religious, agricultural, labor, cooperative and similar non profit-making associations

Pharmacy Building to Be Dedicated—The American Institute of Pharmacy, new headquarters of the American Pharmaceutical Association in Washington, D. C., will be dedicated during the annual session of the association, May 7-12. The new building, located on Constitution Avenue, near the Lincoln Memorial, is of white Vermont marble, with twenty-four rooms. In one end will be a pharmaceutical library, in the other a museum depicting 150 years of American pharmacy. The ground floor contains rooms for storing valuable books and documents and for offices. It is expected that the Revision Committees of the U. S. Pharmacopeia and of the National Formulary, the American Association of Colleges of Pharmacy and other professional organizations will have quarters in the building. It was originally planned to include a research laboratory, but the plan was abandoned when a mem-

Headquarters of the American Pharmaceutical Association

ber of the association offered to build a separate building for this purpose. The main doors and outside lighting fixtures are of bronze. Panels on each side of the main entrance will hold decorations illustrating the history of pharmacy. Henry A. B. Dunning, Pharm. D., Baltimore, is chairman of the building committee and others associated with him in completing the undertaking have been Samuel L. Hilton, Pharm. D., Eugene G. Eberle, Pharm. M., and Evander F. Kelly, Pharm. D., all of Washington, Robert L. Swain, Baltimore, and James H. Beal, Se. D., Fort Walton, Fla.

CANADA

Banting Research Foundation—During the past year twenty research workers received grants from the Banting Research Foundation, according to a report in *Science*. Grants have been made during the six and a half years of the fund's existence to sixty-three workers, principally in Canadian universities. It also aids in the support of the department of medical research of the University of Toronto, under the direction of Dr. Frederick G. Banting. The capital sum now amounts to about \$700,000.

Vancouver Summer School—The annual Vancouver Medical Association summer school will be held, June 26-29, at the Hotel Vancouver. Speakers will be Dr. Frank W. Lynch, San Francisco, obstetrics and gynecology, C. E. Dolman, Dr. P. H., Toronto, laboratory problems, Drs. Howard C. Naffziger, San Francisco, surgery, Max Cutler, Chicago, Walter C. Alvarez, Rochester, Minn., gastro enterology, and Charles A. Aldrich, Winnetka, Ill., pediatrics.

New Radium Source Reported—Newspapers reported April 6, that a new deposit of pitchblende giving promise of a greater supply of radium has been discovered in the Beaver Lake area of Northwest Territory. Since the discovery of radium ore at Great Bear Lake four years ago Canada has become a producer of radium, several thousand milligrams having been produced by the refinery at Port Hope, Ont. which operates the deposits at Great Bear Lake. The province of Ontario has purchased several hundred milligrams for use in its cancer clinics. A recent statement from the government department of mines points out that, contrary to a general belief, the government has no connection with the commercial production of radium. The department of mines devised the method used in treating the ores and mapped the area but it has no control over production or prices.

New Legislation for the Labeling of Food

New legislation on food qualities and food contents will be recommended by a departmental committee, which has just drafted its report. It advises that parliament shall empower the minister of health to make orders as to the contents and qualities of particular foods on the findings of an advisory committee, which shall consult the interests affected and hear evidence. In the event of a uniform standard being suggested, the committee would adjudicate and lay its conclusions before the minister of health. Bread, jam, meat paste, egg powder, custard powder and ice cream are among the great range of commodities that might come under such a procedure. At present, legal standards have been adopted for a few articles, such as milk, butter, cream and margarine. There are in existence already regulations limiting the proportion of preservatives in certain products and provisions in the food and drugs act against the sale of articles "not of the nature, substance and quality demanded." But the interpretations of public analysts as to what is a genuine article vary from district to district, even with regard to cheese, for instance. The matter has been under consideration since 1931. Authorities on food values declare that parliament cannot delay action much longer, as it is astonishing how many kinds of food are sold under names that give the housewife no guaranty of what she gets for her money. The commonest example is "bread," a word that may mean almost anything.

The Contraceptives Bill

In the house of lords, Lord Dawson (president of the Royal College of Physicians) moved the third reading of his contraceptives bill (*THE JOURNAL*, March 10, p. 780) to control the public exhibition of drawings and diagrams of contraceptives and their sale in streets and other public places by means of hawking and automatic machines, these being regarded as an offense against public manners. He considered that the best way of dealing with evil was to promote good, and the best way of dealing with contraception was to remove the atmosphere of falsity that surrounded it. If a ballot should be taken among married persons under the age of 40 he thought that three fourths or more would desire to be in a position to regulate the numbers and spacing of their families. How otherwise was to be explained the steady fall in the birth rate? He appealed to the ministry of health to permit a wider discretion to local authorities, so that birth control instruction might be given to married women. This would direct the movement into regular channels and save newly married women, medically unfit for pregnancy, from endangering their lives. The bill was passed.

Increase in Road Accidents

Notwithstanding all attempts to prevent road accidents, the number for 1933 shows a substantial increase. In Great Britain last year 7,202 persons were killed on the roads, compared with 6,667 in the previous year, and the total number injured was 216,328, compared with 206,450. The accidents numbered 191,782, compared with 184,006. The figures for England and Wales alone are still more unsatisfactory, for in Scotland there was a decrease of one in the number killed. The number of accidents resulting in killed or injured in England and Wales was 175,738, compared with 167,752 in the previous year. The killed numbered 6,498, against 5,962, the injured 198,539, against 188,680. There is, of course, a demand that something more

be done. The government is about to introduce at once a new road traffic bill, of which the following are the principal proposals. A 30-mile limit for private automobiles and motorcycles in "built-up areas" (defined as an area where a system of street lighting is maintained), with lower limit for heavier goods vehicles. The erection of traffic signs if an unlighted length of road is subject to, or a lighted length of road exempted from, the 30 mile limit. The number of separate speed limits to be reduced from six to four. A conviction for exceeding the speed limit or for careless driving to be endorsed on the driver license. A person convicted of careless driving to be liable to disqualification for one month on a first conviction and three months on a second. A new applicant for a driver's license must satisfy the authority of his competence to drive. The use of horns and similar appliances to be regulated. Pedal cyclists may be required to paint a white patch on the rear mudguard. Reflectors not complying with the statutory requirements as to optical efficiency must not be sold. Local authorities may establish crossing places for pedestrians, to be complied with under penalty of a fine. It is claimed that this system has been a great success in Paris. In a broadcast the minister of transport appealed for the exercise of caution. The National Safety First Association has begun a six months intensive campaign, for which it has received a grant of \$25 000 from the Road Fund. A sound film has been produced for children and already has been shown to 500,000. A new series of posters and instructional matter are in hand for use in schools.

The Village Settlement Treatment of Tuberculosis for Ex-Service Men

The treatment of tuberculosis in village settlements, introduced by Sir Penderill Varrier-Jones, under which patients live with their families and carry on industries, has been described in previous letters. The first settlement was at Papworth in Cambridgeshire and proved so successful that it has been taken as a model. Preston Hall, near Maidstone, was established as a settlement for ex-service men. It comprises three sections—the sanatorium, the training center and the settlement where ex-patients live with their wives and children while earning a living at industries. The village population numbers 902 and is made up as follows: sanatorium 250 patients, staff, 58; settlement, 594. Printing is one of the industries carried on in the settlement, and the excellent printed report is a specimen of the work done. Dr J B McDougall, the medical director, insists on the importance of after-care in the treatment of tuberculosis and shows the exceptional advantages of the village settlement for this. But he does not consider the village settlement as the solution for the eradication of tuberculosis in this country. He criticizes the view that the village settlement should continue to provide security for tenure in employment for indeterminate periods, regardless of the clinical condition and suggests how the scheme can be made available for a larger number of patients who are likely to derive medical benefit from prolonged after-care. The essential object of the village settlement in the treatment and after care of pulmonary tuberculosis is to bring the active disease to a state of arrest for a period sufficiently long to reduce liability to relapse to a minimum. But the settlement should not become a center for the employment in perpetuity of arrested cases.

The Lowest Birth Rate on Record

In the last twenty years the recording of the lowest birth rate ever known since statistics on this matter have existed has become monotonous. The rate for 1933 is 14.4 per thousand of population and the lowest ever recorded. It was also the lowest for the fifth year in succession. The death rate was 12.3 and the mortality of infants under 1 year 64 per thousand live births.

Staphylococcus Vaccine in Treatment of Herpes Zoster and Varicella

Dr Pacreau of St Nazaire has recently made a contribution to the subject of staphylococcus vaccine in the treatment of herpes zoster and varicella, which appears decisive. In eighteen months he treated twenty-five cases of herpes zoster by this method with success. The injections are made every two days. The first dose in normal subjects is 0.5 cc, then, depending on the case, one can renew the dose or increase it to $\frac{3}{4}$ cc and then to 1 cc. Three injections generally suffice to effect a permanent cure. The author prefers a stock vaccine that contains staphylococcus anatum. In cases of herpes zoster thus treated, from the first injection of vaccine, the pains diminish and sometimes disappear completely in forty-eight hours, and the patient regains his sleep. The extension of zosterian dermatitis is checked and often the vesicles diminish in size and begin to dry up. As a rule after the second injection there is no longer any sensitiveness of the skin nor neuralgia. The vesicles are transformed into brownish crusts loosely adherent, which, as they drop off, leave a normal pink epidermis. A third injection in about half of the cases, was made to insure the cure. How does the antistaphylococcus vaccine act in herpes zoster? It does not seem likely that it is through the febrile reaction, for numerous cures have been effected without the slightest general reaction having been observed. Furthermore Dr Craps in Brussels had previously discovered that injections of foreign proteins (horse serum) do not produce any result whatever. Recently Dr Pacreau observed an etiologic connection between herpes zoster and varicella. In one family, herpes zoster was diagnosed in the mother, and about twelve days later the two daughters and the father developed typical varicella, which in the father became infected and generalized, nevertheless a cure was quickly effected by vaccinal and local treatment. While it is impossible to say to what extent each of these treatments contributed to the patient's recovery, the author thinks that, while the external treatment facilitated the disappearance of pyodermitis the vaccine doubtless combated effectively the varicella. The author says that, of all the common treatments—local dressings with or without analgesics, internal medications, autohemotherapy—none can give such rapid and good results as antistaphylococcus vaccination.

Suboccipital Puncture

Suboccipital puncture was used at first only by neurologists but it is coming to be used more generally throughout France and some physicians prefer it to lumbar puncture. Mr Basch who discussed this method before the Société des médecins des hôpitaux de Paris, stated that with this method one can easily follow the variations of the cerebrospinal fluid of syphilitic patients under treatment. The accidents due to faulty technique are exceptional if the mastoid processes are properly taken as the bench marks. This puncture gives no meningeal reaction and no secondary headache. Mr Basch gave his observations on forty-eight punctures that he performed and he confirmed the favorable opinion previously expressed by Mariano Castex and P Ravaut. A general discussion followed before the society from which it appears that suboccipital puncture has given satisfaction to all who have used it but that prudent reservations should be made as to its generalization among inexperienced persons. There were however some opponents. Mr Guillaum held that lumbar puncture is preferable to suboccipital puncture for the latter does not furnish all the necessary information in medullary disorder. Mr Combarac preferred

lumbar puncture and called attention to the danger of puncturing the bulb, but Mr. de Genns replied that such an error is anatomically impossible.

The Annual Art Exhibit of Physicians

The Salon des medecins is an annual exhibit of paintings, sculptures and engravings made by physicians. This exhibit was established forty years ago and is always a success. It is held early in March and attracts even the professional art critics, who write it up in the daily press. All profits from the sale of tickets and from entry fees (\$6) go to the support of the Maison du medecin, a home for aged physicians. The exhibit this year was unusually good. Works also of widows, wives, daughters and sisters of physicians are admitted. There were a number of humorous drawings and caricatures. The sculptures, although fewer in number, had higher artistic value. Dr. Sabouraud, the dermatologist, is an excellent artist whose works have attracted attention at the exhibits. A place was reserved this year for the exhibit of medallions engraved by Professor Hayem, who died recently at the age of 90. He was a remarkable engraver.

Death of Professors Pinard and Bousquet

Professor Pinard died recently, following a cerebral congestion, at the age of 90. An eminent obstetrician, he is regarded in France as the father of puericulture. His professional card bore simply the words "Dr. Pinard, puericulteur." A pupil of Tarnier, he was professor of obstetrics and gynecology at the Faculte de medecine de Paris, a member of the Academy of Medicine, and Grand Officer of the Legion of Honor. Before his death he was able to witness the opening of the Institut de puericulture de la Faculte de Paris, the creation of which he had long since demanded. In 1919 he was elected member of the chamber of deputies for Paris. He presented an extensive program designed to raise the birth rate, which however he was unable to get parliament to adopt. His health was excellent, among the members of the Academy of Medicine, his age was surpassed only by Dr. Gueniot, who is now 102 years old.

Likewise the death of Professor Bousquet, former superintendent of the Ecole de medecine de Clermont-Ferrand, an eminent surgeon and the author of numerous classic works, at the age of 82, is announced. Bousquet began his career as a military surgeon.

BERLIN

(From Our Regular Correspondent)

March 5, 1934

Some Restrictions on Private Practice Removed

Some important regulations pertaining to the *krankenkassen* (THE JOURNAL, Dec. 30, 1933, p. 2132) have been recently introduced. The last of the ambulatoriums of the *kranken-kassen* (which existed in Berlin) were closed by the end of 1933. Thus an unsatisfactory institution, which the medical profession had constantly combated ever since its creation during the postwar years, on the ground that it did not constitute a well ordered individual system of treatment, has come to an end. Economic objections were likewise urged against the system, for the physician should be free to practice as he chooses and should not be an officer employed by the *kranken-kassen* and dependent on their behests. Hours of service, in the relationship of an employee, are not in keeping with the ethical and practical tasks of the medical profession. By this new regulation the treatment of the families of the members of *kranken-kassen* has been finally restored to physicians who are free to practice as they see fit. Only a few diagnostic institutes, chiefly for serologic and bacteriologic experiments, will remain open.

In Greater Berlin the dispensary, which imposed extensive restrictions on the practicing physician in the prescribing of

medicines, has been abolished. The Berlin dispensary had frequently been severely criticized by experts in that field. The prescribing of medicines and remedies is still controlled, however, by the "Richtlinien für die wirtschaftliche Verordnungsweise," which was set up by the federal commission on physicians and *kranken-kassen* and has been frequently amended and improved during recent years. The financial side of the prescribing of medicines and remedies has been regulated by an agreement entered into by the *Kassenärztliche Vereinigung Deutschlands* and the league of the *kranken-kassen*, whereby a fixed norm for the average consumption of these substances is established. In Berlin the established norm for general practitioners (which includes office requirements) is fixed at 4 marks (\$1.52) for each case treated. The norms for the other groups of physicians are likewise fixed. If the cost of the medicines and remedies prescribed by a panel physician exceeds by more than 20 per cent the norm established for his group, he must pay the excess amount, it being deducted from his share of the total compensation. These sums are then turned over to the *kranken-kassen*. The law provides, however, for certain exceptions, for example, in the event of a small number of cases treated (under fifty), because a strict application of the law would work a hardship on the physician concerned, and likewise in cases of disease of a peculiar type. Furthermore, the deduction of the excess sum may be omitted if the later activities of the physician concerned have been kept within the limits prescribed and the discovered excess amount has been compensated for.

The following articles may not be prescribed for *kranken-kassen* patients: wine and other alcoholic beverages without pronounced therapeutic effect (except in cases of threatened danger to life), bottled drinking waters without marked therapeutic effect, effervescent mixtures without marked therapeutic effect, artificial bath improvers without marked therapeutic effect, which serve mainly to aromatize the bath water, cosmetic applications that serve for the cleansing, staining or beautifying of the skin, the hair, the nails, the teeth or the mouth cavity, of healthy persons, preparations that serve to arouse the sexual impulse, preparations that serve as contraceptives, remedies or devices to induce abortion, even though they have been advertised as remedies in menstrual disorders, remedies to combat drunkenness, preparations that contain medicine in candy form, with the exception of quinine chocolate wafers for children, preparations intended for the public, which are marketed often by the producer himself, and preparations listed officially as "patent medicines." This list may be changed from time to time.

By economical treatment is meant that the physician is under obligations to treat his patients adequately and in a practical manner. He must refuse all treatment that is not necessary and must prescribe all therapeutic measures, particularly medicines and cordials, in an economical manner. He must protect the *kranken-kassen* against expenditures so far as the nature of the service to the patient permits. The treatment must not go beyond what is necessary. The issuance of certificates with regard to incapacity to work must be based on a conscientious appreciation of the existing conditions. This definition has been expressly emphasized in the agreement mentioned. The *kranken-kassen*, in turn, agree to use their utmost endeavors to induce the insured to make economical use of the *kranken-kassen*.

If the *kranken-kasse* has reason to believe that a panel physician is not heeding the established requirements and is going beyond reasonable needs or thinks that he does not treat patients properly, it may appeal to the *vereinigung* and demand an investigation. The activities of the *kranken-kassen* are further supervised by an examining board appointed by the

Kassenärztliche Vereinigung, in the deliberations of which the Krankenkassen may participate through their medical representatives

A new announcement concerning admission to Krankenkassen practice is of interest. A rumor has been circulated that elimination of all women from medical practice is contemplated. That is not the case, but admission of women to medical study, and likewise the licensure of women physicians and their location in a medical practice, are under the control of the authorities. The medical organizations have no say in the matter. With respect to admission to panel practice, it is provided that men and women physicians shall be temporarily suspended from panel practice if they or their spouse have an income from other sources amounting to at least 500 marks (or correspondingly more if there are children in the family). No special regulation applicable to women physicians is contemplated. With regard to new admission to panel practice, married applicants will be given preference, and married applicants who have children will be accepted first. A recent regulation provides that in Berlin (likewise in many other cities) physicians may not hold consultation hours and receive patients at two different places.

The Economical Use of Expensive Drugs

The economical use of expensive drugs was recently discussed by Dr. Rudolf Hopmann before the Allgemeiner Aerztlicher Verein in Cologne. With regard to the prescribing of insulin, for example, it is not correct merely to ask, "What is the smallest dose that will be effective?" The whole situation must be taken into account, with the idea of restoring the patient's working capacity even with the use of considerable quantities of insulin, for example when the prescribing of strict diets is out of the question. In principle insulin therapy should be preceded by a purely dietetic treatment. In the presence of a constitution characterized by corpulence and sthenia, days of severe diet may be kept up longer than in the case of lean persons. In dealing with the latter if there is danger of acidosis, insulin had better be prescribed, the days of severe diet be omitted and a moderate diet, with at least 100 Gm. of carbohydrates, instituted. The insulin requirements must generally be based on the actual amount of sugar in the twenty-four hour specimen of urine and on the fasting blood sugar. The insulin deficit must, however, be regarded as permanent and continuous. Even the damaged islands of Langerhans produce a certain quantity of insulin. These can be stimulated by special treatment interspersed protein and carbohydrate days, and von Noorden's so-called zigzag diet. In some diabetic persons, muscular activity improves insulin utilization. The best method of administering liver extracts is by intervals of action and repose. The intervals may be several weeks or even months in length. The cost of this method of injection as compared with peroral liver treatment considering both the factors time and effect is as 15 to 75.

Observations on Electrosurgery

Prof. K. H. Bauer, professor of surgery at the University of Breslau, has reported on 500 operations performed by electrosurgery. By histologic sections it was shown that although the process of wound healing was slower than with the scalpel incision and in some instances complicated by later hemorrhages (on the fifth day) it was marked by fewer evidences of infection, by accelerated regeneration and by relative absence of operative shock. The question is: "What patients may be operated on better with the electric knife than by the older method?" The new method appears to be adapted especially to papillomas of the bladder, divisions of the cord with the aid of the thoroscope and coagulation of the gas-trian ganglion.

also to operations on "bleeders," operations on parenchymatous organs, in total removal of malignant tumors. As cancer cells appear to be more sensitive to heat than other cells, good results were possible also in nonradical procedures, reinoculations are avoided and recurrences can be attacked anew after several previous operations.

Reduction of Occupational Diseases

According to the annual reports of the industrial unions, the occupational diseases showed a decline between 1929 and 1932. In 1929, 22,258 cases of occupational illness were reported, the number was reduced, in 1932, to 6,493. In 1930 the number of compensated occupational disorders reached the maximum, whereas in 1932 the number was reduced to 1,711. The decline is due partly to the introduction of legal measures and partly to the repercussive effects of the changes in economic conditions. The number of cases of pneumoconiosis reported last year was 605, whereas in 1929 more than 1,750 cases were notified.

Tobacco Consumption in the Netherlands

The consumption of cigars showed a steady increase from 1924 to 1930, but in 1931 and 1932 there was a decrease. The consumption of cigarettes maintains its ascending curve. The consumption per person is increasing for cigars, 146 in 1923, 174 in 1930 and 167 in 1932, for cigarettes, 274 in 1923, 455 in 1930, 444 in 1931 and 450 in 1932. The total value of cigars, cigarettes and tobacco consumed amounted to 142,000,000 florins (\$92,300,000) in 1923, 152,000,000 in 1924, 138,000,000 in 1925, 183,000,000 in 1930, 180,000,000 in 1931 and 163,000,000 in 1932. The cost per person was 19.89 florins (\$14) in 1923, 23.25 florins in 1930 and 20.01 florins in 1932. One observes also in recent years a marked increase in the consumption of cheaper brands of tobacco to the detriment of the better qualities. The number of two-cent cigars rose from 197,175 in 1931 to 279,538 in 1932, whereas the number of two-florin cigars dropped from 6,000 in 1931 to 3,000 in 1932.

An Emblem for Physicians' Automobiles

The commission appointed by the government to select an emblem for physicians' automobiles has chosen the caduceus with a serpent coiled about it. As to the significance of the emblem there are now many emblems recognized locally, the holders of which enjoy certain privileges, for example, the right to exceed the speed limit, priority of passage on ferryboats and parking in places otherwise prohibited. But these privileges have little value unless there is a traffic officer present to enforce them. On the open highways there are no traffic officers, so that these privileges are of little avail. The commission does not deem it desirable to attach to this insignia any special obligations. Every automobilist from whom one requires aid on the highways must stop whether he is a physician or not and whether or not the car bears a special emblem. From that point of view instead of relying on an emblem that is too small to be noticed on a rapidly moving car it would be preferable to agree on a signal (for example, a handkerchief held in an extended arm) which would signify "If a physician please stop." The installation along the highways, of aid stations supplied with surgical dressings and equipped with a telephone would be equally desirable. The commission ends its report with the following conclusion: adoption of an emblem for the simple purpose of bringing the automobilists and physicians together without attaching thereto any special privileges or obligations, and the possible internationalization of the emblem.

Statistics on Cremation

T Van Den Brink gives, in the *Mensch en Maatschappij*, statistics on cremation in the Netherlands and in other countries. The Association for Optional Cremation was founded in 1874. The first cremation occurred in 1914. Progress has been more rapid in recent years. From a total of 262 in 1925 the number rose to 555 in 1931. During the first eleven months of 1932, 585 bodies were cremated. In 1931 the percentage had not yet reached 1 per cent, there having been 555 cremations and 77,000 deaths. This figure is much lower than that of other countries. In 1930 the number of cremations per thousand deaths in various countries was as follows: Japan, 494, Argentina, 135, Switzerland, 106, Germany, 76, Denmark, 44, Austria, 43, Norway, 41, Czechoslovakia, 23, Sweden, 14, England, 10, Netherlands, 7, and France, 2. Switzerland, in spite of its small population and restricted area, has twenty crematories. By the end of December 1930 the number of members in the Association for Optional Cremation had risen to 9,000, representing about 35,000 advocates of cremation. The Netherlands is today the only country of Europe that has no law regulating cremation. By its refusal to recognize cremation officially, the government seems to stamp it as illegal. It is surprising that no attempt has been made to regulate the question by a modification of the law of 1869 in regard to burials.

The Public Health in Dutch Guiana

From a comparison of the mortality figures in the metropolis and in Dutch Guiana, it is evident that the number of deaths from unknown causes is still high in the colony, particularly from cancer, which is much less often recognized than in the Netherlands. Vaccinations against infectious diseases, and the surveillance of schools, have given encouraging results. More than 26,000 patients took a course of treatment for trichinosis in 1932. The crusade against leprosy has been active. Patients have been compelled to accept treatment and if necessary isolation in a leprosarium, special schools for leprous children makes it possible to treat patients promptly. Free treatment in the polyclinics has been instituted for venereal diseases. Dr Lampe has pointed out that the effectiveness of arsphenamine and bismuth compounds in the treatment of syphilis seems to be decreasing owing to the appearance of more resistant forms of virus.

Aid for Foreign Physicians

The recent events in Germany are the cause of so many Jewish physicians being obliged to leave Germany and being without resources. Dutch physicians have appointed a commission that, aside from all political considerations, will endeavor to support the morale and undermined financial status of their unfortunate colleagues. The new regulations of the Netherlands no longer permit foreigners to hold the position of assistant in a hospital or a laboratory. In the hope of aiding their confreres, the Dutch physicians have sent letters of inquiry to other countries to ascertain whether these physicians can secure permanent openings there.

Foreign Students

A large number of foreign students have come to our universities. The government is considering the erection of certain barriers to the admission of foreign students. The minister of public education has pointed out that this increase in foreign students required additional expenditures for laboratories and that the places in the laboratories and hospitals were often occupied by them. He thinks that this danger must be combated as soon as possible by excluding all foreign students from enrollment in the universities and higher schools of learning.

Protest Against Free Service to the Rich

The recently founded Colegio de Medicos has studied various professional problems, which are discussed in *Revista*, the official journal of the association. The principal activities of the members have up to the present been concentrated on hospital problems. The city, the government and several private institutions support free hospitals, where anybody who presents himself at the institution is taken care of. Many of these persons are well to do, some are even rich. The physicians serving in those hospitals receive no salary or at best very small salaries. There is a large number of patients in proportion to the number of physicians, for instance, at the Rawson Hospital 16,000 hospital patients and 284,000 outpatients were treated in one year by only twenty-four physicians. Each pharmacy assistant filled 230 prescriptions in one day. It is impossible to do good work. The members of the Colegio de Medicos hold that free hospital service by the city or the government should be given only to the poor, patients whose incomes vary from 160 to 350 pesos a month, according to the size of their families. For obstetrics and surgery, the basis of the calculation would be raised one third. Free services are attacked because they demand from the state resources beyond its means and compel physicians to serve without remuneration people who can pay. The members of the Colegio de Medicos hold also that assistant physicians and heads of departments should have adequate remuneration. As a result of these negotiations the city of Buenos Aires passed a law of graduation of physicians in the hospitals. Down in the scale is the assistant physician, who obtains appointment by passing an examination, five years later he may be assigned as an associate physician. There will be a physician for each twenty beds in a hospital. The head of a department is appointed for ten years. Besides these there will be intern physicians assigned after examination. Each hospital will have its own medical director, a position obtained only by promotion from the lower to the immediate position.

Another problem studied by the Colegio de Medicos was the economic and professional relations between physicians and institutions of mutual aid and welfare, many of which are flourishing but pay little to the physicians who work for them and are the bases of their activities.

Institute for Diagnosis of Neoplasms

An institute for the diagnosis of neoplasms, supported by the centers of public welfare and sanitary administration of the federal capital was inaugurated February 9 in Buenos Aires, with Dr Domingo Mosto, associate professor of pathologic anatomy of the University of Buenos Aires, as director. This institution will make all biopsies and examine all specimens sent by physicians or by municipal hospitals. The purpose is to obtain early diagnosis with the aim of an early treatment of cancer. Besides this municipal institution there is at Buenos Aires the Instituto de Medicina Experimental, with Dr A. H. Roffo as director. This institution is exclusively for the study of cancer and it is supported by the national university of Buenos Aires and by the national government of Argentina. It is equipped with wards, polyclinics and laboratories.

Death of Professor Iribarne

Dr J. Iribarne, professor of gynecology of the Faculty of Medicine of Buenos Aires, aged 49, died as result of an automobile accident. Twice he was dean of the Faculty of Medicine of Buenos Aires. He was also an organizer of medical and social works. He was president of the Argentine Social Museum and the editor of several medical journals.

Marriages

EVERETT WALKER McCauley, Burlington, N C, to Miss Ella Irene Wilson of Townesville, February 2

LUCIUS H BRACEY, South Hill, Va, to Mrs Gladys Yancey Bramham of Durham, N C, February 22

RICHARD ADDISON THAYER to Miss Barbara F Pierson, both of Beloit, Wis, February 24

DUDLEY CIRCUS BABB, Baltimore, to Miss Margaretta Laurenson Lackey, April 2

HUGH P GREELEY to Mrs Mark Trövell, both of Madison, Wis, March 23

Deaths

Jacques Holinger @ Chicago, Universität Basel Medizinische Fakultät, Basel, Switzerland, 1892, member of the American Otolaryngological Society, associate professor of laryngology, rhinology and otology, University of Illinois College of Medicine, aged 68, on the staffs of the Alexian Brothers' Hospital, Illinois Masonic Hospital, Grant Hospital and St Joseph's Hospital, where he died, March 30, of coronary occlusion

Earle Russell Hare @ Minneapolis, University of Minnesota Medical School, Minneapolis, 1900, at one time secretary of the Minnesota State Medical Association, member of the Western Surgical Association and the American Association of Anatomists, formerly instructor in anatomy and surgery at his alma mater fellow of the American College of Surgeons, surgeon to St Barnabas Hospital, aged 61, died, April 8

Richard Jordan, New Canaan, Conn, Medizinische Fakultät der Universität Leipzig, Saxony, Germany, 1895, member of the American Otolaryngological Society, fellow of the American College of Surgeons, formerly visiting otolaryngologist to the Lenox Hill Hospital and the Fifth Avenue Hospital, New York, aged 64, died, February 5, in the Polyclinic Hospital, New York, of pulmonary embolus

William Crissey Kellogg @ Augusta Ga, Johns Hopkins University School of Medicine, Baltimore, 1900 professor of clinical ophthalmology and otolaryngology, University of Georgia Medical Department, fellow of the American College of Surgeons, on the staffs of the Lamar Hospital and the Wilkenford Hospital for Women and Children, aged 59, died February 14, of pneumonia

Ernest White Patton @ Chattanooga Tenn, University of Nashville Medical Department, 1908, fellow of the American College of Surgeons, past president of the Chattanooga and Hamilton County Medical Society, on the staffs of the Baraness Erlanger Hospital and the Newell and Newell Sanitarium aged 52, died suddenly, March 15, at his home in Lookout Mountain, of heart disease

Archibald Byron Macallum, London, Ont Canada University of Toronto Faculty of Medicine, Toronto 1889, emeritus professor of biochemistry, McGill University Faculty of Medicine, Montreal, formerly lecturer and professor of physiology and biochemistry at his alma mater member of the Association of American Physicians aged 74 died, April 5

Willis Bryant Jones, Atlanta, Ga, Columbia University College of Physicians and Surgeons New York, 1901 member of the Medical Association of Georgia, on the staffs of the Grady, Crawford W Long, Wesley Memorial and Georgia Baptist hospitals, aged 59, died, March 3, in the Union Memorial Hospital, Baltimore, of intestinal obstruction

Henry McMahon Painter, New York College of Physicians and Surgeons in the City of New York Medical Department of Columbia College, 1888, formerly professor of clinical obstetrics at his alma mater consulting obstetrician to the Sloane Hospital for Women, aged 71, died March 11 of chronic myocarditis

Clarence Clifton Miles, Greenport, N Y College of Physicians and Surgeons Medical Department of Columbia College New York 1876 member of the Medical Society of the State of New York, formerly coroner and bank president aged 79 died March 8 at the home of his daughter in West Newton Mass

Roscoe William McKinley, Burlington Wash National University of Arts and Sciences Medical Department St Louis 1917 member of the Washington State Medical Association

served during the World War, on the staff of the Burlington General Hospital, aged 43, died, March 14, of lobar pneumonia

Snow Parker Freeman Cook @ Gloucester, Mass, University of Pennsylvania School of Medicine, Philadelphia, 1886 member of the New England Ophthalmological Society, aged 71, on the staff of the Addison Gilbert Hospital, where he died, April 6, of ulcerative colitis and cerebral hemorrhage

Monroe David Reese @ Lebanon, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1921, member of the American Academy of Ophthalmology and Oto-Laryngology past president of the Lebanon County Medical Society, aged 37, died, March 22, of carcinoma

James Gordon Bonine, Cassopolis, Mich, Illinois Medical College, Chicago, 1901 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, formerly state senator, aged 57, died suddenly, March 3, in a hospital at Niles, of heart disease

Harry Warren Lincoln @ Brooklyn, Long Island College Hospital, Brooklyn, 1894, on the staffs of the Jamaica Hospital, Richmond Hill, N Y, Wyckoff Heights and Bushwick hospitals, aged 61, died March 25, in the Brooklyn Eye and Ear Hospital, of heart disease

Adelbert Howard Monty, Woonsocket, R I, Columbia University College of Physicians and Surgeons, New York, 1906, member of the Rhode Island Medical Society, on the staff of the Woonsocket Hospital, aged 50, died, February 9, in Providence, of myocarditis

Charles W Moody, Plainville, Conn, New York Homeopathic Medical College, 1884, at one time member of the board of education, aged 76, died, February 19, in the Bristol (Conn) Hospital, of fracture of the femur, hypostatic pneumonia and hypertrophy of the prostate

Ross Hopkins, Jefferson City Mo, Johns Hopkins University School of Medicine, Baltimore, 1903, member of the Missouri State Medical Association, for many years connected with the state board of health, aged 55, died, March 27, of muscular atrophy

Edward Cole Clavin, San Antonio Texas, University of Pennsylvania School of Medicine, Philadelphia, 1893, member of the State Medical Association of Texas, aged 65, formerly on the staff of the Santa Rosa Infirmary, where he hanged himself, March 3

James Churchill Hanchett @ Detroit, Chicago Homeopathic Medical College, 1888, member of the Utah State Medical Association, medical director of the Maccabees, aged 69 died, March 28, in the Henry Ford Hospital, of erysipelas and acute nephritis

James Marsh McLean, Bay City, Mich, University of Toronto Faculty of Medicine, Toronto, Ont, Canada, 1910 member of the Michigan State Medical Society, aged 47, on the staff of the Mercy Hospital, where he died, February 28 of pneumonia

Issi Otto Pond @ Perry, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City, 1901, past president of the Dallas County Medical Society on the staff of the Kings Daughters Hospital, aged 60, died, March 15, of heart disease

William Holcombe Aiken, Tuscaloosa Ala Tulane University of Louisiana School of Medicine, New Orleans, 1915, served during the World War, connected with the Veterans Administration Facility, aged 50, died, March 11, of heart disease

Melvil S Coxe @ Dunkirk, N Y, University of Buffalo School of Medicine 1904, for many years a member of the local board of health on the staff of the Brooks Memorial Hospital, aged 56 died, April 8, of cerebral hemorrhage

John Gill Lilly, Tupelo, Miss, Tulane University of Louisiana Medical Department New Orleans, 1899, member of the Mississippi State Medical Association, on the staff of the Tupelo Hospital, aged 61, died March 1, of heart disease

Reginald David Graham @ Duluth Minn Chicago College of Medicine and Surgery 1915, on the staff of the Duluth Hospital aged 49 died Dec 26 1933 of carcinoma which developed in roentgen burns of the hands

William Horner Gardner, Pittsburgh Western Pennsylvania Medical College Pittsburgh 1899 member of the Medical Society of the State of Pennsylvania aged 72 died March 23 of hypostatic pneumonia

George William Lewis Wilson N C University of Maryland School of Medicine Baltimore, 1895 member of the Medical Society of the State of North Carolina aged 70 died February 16 of arteriosclerosis

Arminius Hank Evans, Saxton, Pa., Medico-Chirurgical College of Philadelphia, 1892, member of the Medical Society of the State of Pennsylvania, formerly member of the school board, aged 76, died, March 5, of cerebral hemorrhage.

Frank Baker Hiller ♂ Kansas City, Mo., Rush Medical College, Chicago, 1891, formerly secretary of the state board of health of Missouri, served during the World War, aged 64, died, March 18, of heart disease.

Calvin Hawthorne Childress ♂ Norfolk, Va., Medical College of Virginia, Richmond, 1915, served during the World War, aged 42, died suddenly, April 1, on board the steamship *Robert L. Lee*, of angina pectoris.

Theodore E. Ingram, Marietta, Pa., Jefferson Medical College of Philadelphia 1885, member of the Medical Society of the State of Pennsylvania, aged 75, died, April 2, in a hospital at Wernersville.

John Cornelius Klutho, Los Angeles, Missouri Medical College, St. Louis, 1898, member of the California Medical Association, aged 58, was found dead March 16, of a self-inflicted bullet wound.

Joseph Muir, New York, University of the City of New York Medical Department 1884, aged 69, died, February 8, in the Mount Sinai Hospital, of chronic nephritis, uremia and chronic myocarditis.

A. Jerome Hermann, Middleburg, Pa., Medico-Chirurgical College of Philadelphia 1897, for many years county coroner, aged 62, died, March 10, in the Geisinger Memorial Hospital, Danville, of uremia.

Wyllis K. Ingersoll, Philadelphia, New York Homeopathic Medical College, 1879, aged 77, on the staff of the Hahnemann Hospital, where he died, March 23, of carcinoma of the prostate.

Ottis Dee McCoy, Wheeling, W. Va., College of Physicians and Surgeons, Baltimore, 1904, member of the West Virginia State Medical Association, aged 56, died, March 13, of pneumonia.

John Joseph Ogle, San Diego, Calif., Bennett College of Eclectic Medicine and Surgery, Chicago 1890, aged 87, died, February 4, in the Patton (Calif.) State Hospital, of chronic myocarditis.

Minot Kniffin Kellogg, Augusta, Ga., University of Georgia Medical Department, Augusta 1933, intern at the University Hospital, aged 24, died, February 10, of lobar pneumonia.

August George Ludwig Rindler, Davenport, Iowa (licensed in Iowa in 1887), aged 80, died, March 22, in the Mercy Hospital, of injuries received when struck by an automobile.

Maurice Markel, Pittsburgh, Jefferson Medical College of Philadelphia 1929, aged 35, died, January 14, in St. Francis Hospital, Miami Beach, of injuries received in an automobile accident.

Thomas Eugene Keaveney, Keithsburg, Ill., Creighton University School of Medicine, Omaha, 1926, aged 32, died, March 24, in the Mercy Hospital, Burlington, Iowa, of brain tumor.

Albert H. Gilbrech, Clarendon, Ark., Illinois Medical College, Chicago, 1904, member of the Arkansas Medical Society, aged 58, died suddenly, February 27, of coronary occlusion.

Ulysses Grant Risser ♂ Campbelltown, Pa., Jefferson Medical College of Philadelphia, 1897, aged 62, died, February 10, of carcinoma of the lesser curvature of the stomach.

Rufus Acos Harlan, Hillsboro, Iowa, College of Physicians and Surgeons, Keokuk, 1878, Hahnemann Medical College and Hospital, Chicago, 1884, aged 80, died, February 24.

Allen Morris Kincheloe, Hardinsburg, Ky., Kentucky School of Medicine, Louisville 1870, formerly county health officer, aged 86, died, March 6, of cerebral hemorrhage.

Horace Rinaldo Minnick, Bellflower, Mo., Cincinnati College of Medicine and Surgery, 1879, member of the Missouri State Medical Association, aged 80, died, February 14.

Alexander Boyd Montgomery ♂ Long Beach, Calif., Rush Medical College, Chicago 1897, served during the World War, aged 63, died, March 11, of acute septic arthritis.

Joseph Exter McDowell, National Military Home, Calif., University of Nashville (Tenn.) Medical Department, 1905, aged 57, died, January 4, of carcinoma of the prostate.

Daniel Gordon Milton, Webster, Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1907, aged 62, died, March 3, of angina pectoris and arteriosclerosis.

Fred Howard Heming, Meaford, Ont., Canada, University of Toronto Faculty of Medicine, 1892, local medical health officer, aged 63, died, January 3, of heart disease.

Charles Wesley Card, San Francisco, Cooper Medical College, San Francisco, 1884, aged 76, died, February 11, of cerebral hemorrhage and arteriosclerosis.

John J. Rife, Boston, Ind., Cincinnati College of Medicine and Surgery, 1869, for many years health officer of Boston, aged 92, died, February 17, in Richmond.

James Bethuel Keith, Imperial Beach, Calif., University of the City of New York Medical Department, 1894, aged 64, died, March 12, of cerebral hemorrhage.

William Raseboom Abbott, Cincinnati, Miami Medical College, Cincinnati, 1908, on the staff of St. Mary's Hospital, aged 49, died, March 26, of pneumonia.

Mary Temperance Cole, Monmouth, Ore. (licensed in Oregon in 1891), aged 82, died, February 25, in the Salem (Ore.) Deaconess Hospital, of senility.

Julius J. Stagg, Eunice, La., Tulane University of Louisiana Medical Department, New Orleans, 1898, aged 58, died, February 19, of cerebral hemorrhage.

Albert Jacob Berger, San Francisco, College of Physicians and Surgeons of San Francisco, 1904, aged 56, died, February 10, of chronic bronchitis.

Frank Wesley Carpenter, San Francisco, Cooper Medical College, San Francisco, 1894, aged 63, died, January 31, of arteriosclerosis and heart disease.

Milton R. Fisher, Palmyra, Pa., Jefferson Medical College of Philadelphia, 1877, aged 82, died, March 3, in the Good Samaritan Hospital, Lebanon.

Charles Abraham Mayor ♂ Philadelphia, Temple University School of Medicine, Philadelphia, 1910, aged 54, died, March 23, of heart disease.

Claude A. Dundore ♂ Philadelphia, Jefferson Medical College of Philadelphia 1887, aged 67, died, March 8, of heart disease and nephritis.

Patrick Joseph Mooney, Brooklyn, University of the City of New York Medical Department, 1893, aged 63, died, February 17, of heart disease.

William Gibson Black, Nashville, Tenn., College of Physicians and Surgeons, Baltimore, 1883, aged 76, died, March 26, of thrombosis.

August Schmidt, Los Angeles, Marion-Sims College of Medicine, St. Louis, 1892, aged 69, died, February 15, of carcinoma of the hand.

Ben Russell ♂ Sheffield, Ill., College of Physicians and Surgeons, Baltimore, 1896, aged 70, died, March 14, of acute dilatation of the heart.

Alphonse M. Schnorr, Philadelphia, Jefferson Medical College of Philadelphia, 1908, aged 70, died, March 27, of cerebral hemorrhage.

A. D. Kelly, Covington, Ky., Meharry Medical College, Nashville, Tenn., 1896, aged 73, died, February 26, of acute interstitial nephritis.

John Finland Haas, Kelleys Island, Ohio, Starling Medical College, Columbus, 1896, aged 70, died, February 27, of heart disease.

Leatha Ruth Tyler Frei, Santa Rosa, Calif., University of Oregon Medical School, Portland, 1908, aged 50, died, February 17.

Allen Forrest Latta ♂ Cumberland, Ohio, Louisville (Ky.) Medical College, 1895, aged 60, died, February 22, of coronary occlusion.

Herman Silverman, Los Angeles, Baltimore University School of Medicine, 1896, aged 66, died, March 6, of myocarditis.

David Nelson Bacon ♂ Bakersfield, Calif., Chattanooga (Tenn.) Medical College, 1892, aged 72, died, February 12.

John Ledbetter, Eatonton, Ga., College of Physicians and Surgeons, Baltimore, 1886, aged 78, died, February 3.

Edmund J. Bolio, Detroit, Michigan College of Medicine, Detroit, 1884, aged 87, died, March 1, of pneumonia.

John William Harpster, Anaheim, Calif., Rush Medical College, Chicago 1891, aged 65, died, February 18.

William Taylor McElroy, Beardstown, Ill., St. Louis Medical College, 1872, aged 79, died, March 24.

John R. Piercey, Prescott, Ark. (licensed, Arkansas, 1903), aged 57, died, February 26, of diabetes mellitus.

Correspondence

A FREE IODINE SOLUTION, SIMILAR TO PREGI'S SOLUTION, USED IN THE TREATMENT OF CHRONIC TRAUMATIC AND ARTHRITIC EFFUSIONS

To the Editor —At the annual meeting of the American Orthopedic Association, held at Toronto in June 1932, I read a paper entitled "Clinical and Experimental Observations with Regard to the Injection of Certain Agents, Pregl's Solution, in Chronic Arthritic Joints" This paper was published in the *Journal of Bone and Joint Surgery* (15 483 [April] 1933) and summarized my observations in connection with the use of a solution that I had found described in *Queries and Minor Notes* in THE JOURNAL, Nov 10, 1923, p 1628, in reply to a request with regard to the use of Pregl's solution of iodine in cases of varicose veins, and the formula was copied apparently from the *Schweizerische Apotheker-Zeitung* 60 322, 350

Having used various dilutions of tincture of iodine with but limited success in certain cases of chronic effusions of the knee joint, with considerable temerity I began to use a preparation following the formula referred to in the preceding paragraph, both clinically and experimentally, with rather satisfying results, particularly when the solution was fresh However as others began to make up and use this solution, it was realized that it did not fulfil the implied requirements of containing from 0.035 to 0.04 per cent of free iodine Nor did it maintain the color test as outlined in *Queries and Minor Notes* I received so many inquiries with respect to these inconsistencies that Don M Bavis, the chemist in my laboratory, began a series of experiments and reviewed much of the available literature He was unable to find the quotation from the *Schweizerische Apotheker-Zeitung* but in the *Zentralblatt für Chirurgie* 49 1050, 1922, R Dittrich and A Herman give a formula for Pregl's solution of iodine which reads exactly the same as the one quoted in THE JOURNAL with the exception that 6 Gm of crystalline sodium carbonate is used instead of 16 Gm The solution made by this corrected formula agrees in every particular with the description that Pregl himself gives and contains a slight excess of free iodine over 0.04 per cent, freshly made up This preparation, kept in a glass stoppered bottle, tightly corked, at room temperature for one month, and checked daily with hundredth normal sodium thiosulphate, maintained the 0.04 per cent free iodine After about one and one-half months under the same conditions and frequent opening of the bottle, there was still 0.035 per cent of free iodine present This solution when kept in an ice chest, would maintain from 0.04 to 0.035 per cent of free iodine for six months Apparently the lack of free iodine and the loss of color in the formula as published and previously used by me was due to the fact that there is an excess of sodium carbonate as the free iodine was rapidly converted into an iodide in the presence of an excess of alkali

I have been using this revised solution in the treatment of certain cases of myofascitis, the report of which, together with bacteriologic observations, is being prepared for publication The correction of this published formula will aid greatly in rectifying the estimated value of this free iodine solution in the treatment of chronic joint effusions

The corrected formula is as follows To 3 Gm of finely powdered iodine in a flask, add 6 Gm of crystallized sodium carbonate or 2.22 Gm of the anhydrous form dissolved in about 30 cc of distilled water Stopper and place in an incubator over night or until all the iodine is in solution The

next day add 4 Gm of sodium chloride and dilute to 1 liter Titrate with hundredth normal thiosulphate If it shows from 0.035 to 0.04 per cent of free iodine, use it as it is If it is too strong, warm gently until it is brought down to that figure Keep in a glass stoppered bottle in an ice chest

J E M THOMSON, M D, Lincoln, Neb

RICKETS RARE IN PUERTO RICO

To the Editor —In THE JOURNAL, March 24, I have noted the editorial comment pointing out that rickets is undoubtedly a rare disease in Puerto Rico In Public Health Bulletin 138, which is a report of the tuberculosis survey of the island of Puerto Rico made by Surgeon J G Townsend of the Public Health Service from Oct 11, 1922 to April 18, 1923, this observation was made The report also contains useful information regarding the prevalence of disease as related to economic conditions

DANGEROUS DRUG REACTIONS

To the Editor —Too little emphasis has been given to the possibility that a drug may have, besides its direct action, an indirect or latent and potential effect Thus, cinchophen appears to cause liver injury only in sensitive individuals, in contradistinction to hydrazine, which produces liver damage in all subjects The recent work of Watkins (*Proc Staff Meet Mayo Clin* 8 713 [Nov 22] 1933) and of Madison and Squier (THE JOURNAL, March 10, p 755) indicates quite definitely that compounds such as amidopyrine and various barbituric acid derivatives can cause granulocytopenia, but unlike the action of benzene, which consistently attacks bone marrow, the condition is produced in only a small percentage of cases There has been a growing tendency to look on this latent toxic action of drugs as allergic In a recent article (*Am J M Sc* 187 155 [Jan] 1934) I proposed the theory that drugs which produce allergic reactions such as urticaria, angioneurotic edema and vasomotor disturbance may perhaps also cause a severe inflammatory reaction, which may terminate in necrosis, such a reaction being comparable to the Arthus phenomenon The acute yellow atrophy of the liver and the bone marrow injury in granulocytopenia may well be explained on this basis Such a concept necessitates accepting the possibility that any drug giving rise to mild allergic signs such as urticaria may in sensitive individuals produce serious visceral damage There is no absolute specificity as to the type of tissue attacked, although cinchophen appears to have a predilection for the liver and amidopyrine for bone marrow Arsphenamine is known to produce both liver and bone marrow injury Undoubtedly other tissues can be affected, Pettit (*Brit M J* 2 442 [Sept 8] 1928) reported a case of pancreatitis that appeared after cinchophen

It is to be emphasized that any drug in which the incidence of urticaria is high should be administered with trepidation One should be fully aware of the potential dangers before using a new drug like alpha-dimethoxyphenol which according to Tainter Stockton and Cutting (THE JOURNAL, Nov 4 1933 p 1472) causes urticaria with fair frequency Even the direct physiologic action is so potent that it should demand the vigilance of a physician trained in recognizing the manifold and often baffling manifestations of drug toxicity It must be recognized that at present nothing is known of the possible late sequelae which in the case of both cinchophen and amidopyrine went unrecognized for many years Judging

from the reports available it is fairly clear that the incidence both of toxicity and of hypersensitivity is manifested by urticaria is much higher for dinitrophenol than for cinchophen. The relatively wide use of dinitrophenol is therefore amazing, since few physicians now have the temerity to prescribe cinchophen. The indiscriminate use of any drug is deplorable but of as powerful an agent as dinitrophenol is distinctly disquieting.

Since drugs can cause obscure pathologic changes, the importance of a careful investigation of the patient's drug habits as an essential part of every anamnesis cannot be stressed too strongly.

ARMAND J. QUICK, M.D., New York

GRANULOCYTOPENIA

To the Editor—I should like to take this opportunity to make an addition to the report of two cases of granulocytopenia, published in *THE JOURNAL*, February 17. After the death of these patients it was discovered that they had used an undetermined, but quite large quantity, of amylol compound, over a fairly long period of time. In the light of recent investigations this fact has seemed to be of possible significance, both in helping to confirm the diagnosis and as an additional link in the chain of evidence against the barbiturates, or amidopyrine, or both, as etiologic agents in this disease.

PAULINE ZINNINGER, M.D., Canton, Ohio

HEREDOFAMILIAL ANGIOMATOSIS WITH RECURRING EPISTAXIS

To the Editor—J. F. Madden of the University of Minnesota Medical School, in his paper on "Generalized Angiomatosis" (*THE JOURNAL*, February 10, p. 442), erroneously states that "hereditary hemorrhagic telangiectasia was first reported by Sutton, in 1864, as internal hemorrhages and telangiectasia of the skin."

Erasmus Wilson, in 1869 called the condition eruptive angiomas. Chiari, in 1883, regarded it as a hemophilia of slight degree, Rendu, in 1896, as juvenile hereditary epistaxis associated with multiple hemorrhagic telangiectasias of the skin and mucous membranes, Ullman, in 1900, as angiomatosis.

Since H. Gawen Sutton of the Metropolitan Free Hospital published his paper on "Epistaxis" (*M. Mirror*, London 1 769-781 [Dec.] 1864), I was the first to refer to his work in my publications.

Sutton discussed the relation of rheumatic fever and tuberculosis to epistaxis and the connection between epistaxis and hemoptysis. He mentions cases of familial hemoptysis and familial epistaxis. But nowhere in his paper does he report a true instance of "heredofamilial angiomatosis (Goldstein) with recurring heredofamilial epistaxis" (Rendu-Osler-Weber's disease). Sutton's cases are no different than those reported by W. Fordyce in 1784 (*Haemorrhagia, Fragmenta Chirurgica et Medica*, London, T. Cadell, 1784, p. 41), J. P. Frank ("Nasenbluten," "Mundblutung," in *Specielle Pathologie und Therapie*, "Forstner and Gerold, Berlin 1 483, 490, 1840), Babington (*Lancet* 2 362, 1865), Verneuil (1894), Gastou (1894) and others. Erasmus Wilson (1869) did not report a typical familial case of Rendu-Osler-Weber's disease. G. Richelot (*Union med* 1 179-180 [April 10] 1847) reported an instance of familial epistaxis.

J. W. Legg (*Lancet* 2 856 [Dec. 16] 1876), Chiari (1883-1887), H. Senator (*Klin. Wchnschr.* 28 1-5 [Jan. 5] 1891) and Henri L. J. M. Rendu (*Bull. et mem. Soc. med. d. hôp. de Paris* 13 731-733 [Oct. 23] 1896, *Gaz. d. hôp.* 69 1322-1323 [Nov. 24] 1896) first differentiated this clinical entity as atypical hemophilia or pseudohemophilia.

Madden overlooked the reports by Fordyce (1784), Elsaesser (1826), Frank (1840), Richelot (1847), J. Wickham Legg

(1876), Senator (1891), and the term "pseudohemophilia" used by Rendu (1896).

Lales (1892), Kennan (1902), Swanton (1907), Bramwell (1907) and Davidson (1907) also reported cases of familial epistaxis, but they do not mention telangiectasias.

Further reference may be made to my publications (*Arch. Int. Med.* 27 102 [Jan.] 1921, 48 836-865 [Nov., part 1] 1931, *Arch. Dermat. & Syph.* 26 282-308 [Aug.] 1932, *Acta Dermatol. Venereologica* 13 661-694 [Dec.] 1932, *Tr. Am. Therap. Soc.* 1932, pp. 47-64, and *M. Times*, London 61 105-107 [July] 1933). In 1930 I first coined and used the name "Rendu-Osler-Weber's disease," which has since been adopted by French writers.

HYMAN I. GOLDSTEIN, M.D., Camden, N. J.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

VINCENT'S INFECTION OF THE MOUTH

To the Editor—I would like to be permitted to take issue with portions of your answer directed to the query entitled "Vincent's Infection of the Mouth" (*THE JOURNAL*, February 24, p. 639).

The majority of the dental profession especially those interested in and devoted to the pursuit of disorders of the oral mucous membrane have in recent years recognized the existence of a chronic Vincent's infection. The literature itself has been replete with references ascribed to this type of Vincent's infection.

Rosenthal says (*J. Am. Dent. A.* 20 438-446 [March] 1933). Some years ago I stated that Vincent's infection was entirely an acute process. Observation of many hundreds of cases and records of colleagues revealed no instance of chronic infection as we understand it today. Now more than 60 per cent of my cases are subacute or chronic. This type of Vincent's infection is painless. It closely resembles periodontoclasia or a gingivitis which will not respond to the usual treatment. Considerably more difficulty is encountered in overcoming chronic Vincent's infection than in combating the acute forms.

Thompson (*J. Am. Dent. A.* 18 1405-1412 [Aug.] 1931) classifies Vincent's infection into two forms acute and chronic. He says: "The chronic form is not characterized by pain or soreness and generally not by any systemic disturbance. Hemorrhage is the outstanding symptom and destruction of the soft tissue is common. There is not local indication of the disease. A smear is positive. Intensive and prolonged treatment is required in these cases." Taylor and Repetto in a discussion of this paper concur in their opinions with Thomson relative to the presence of a chronic type of Vincent's infection.

Merritt says (*Periodontal Diseases*, New York, Macmillan Company, 1930): "There is a form of Vincent's infection lacking in many of the symptoms of the acute type that is very much more common and which is often incorrectly diagnosed. This is the chronic or subacute type in which there is no slough and no marked objective symptoms."

Albray (*Dental Cosmos* 75 878-883 [Sept.] 1931), in a paper delivered before the New York Academy of Medicine states that in some mouths the infection will persist in subacute form for long periods of time, causing only slight discomfort and gradual destruction of the soft tissues and the alveolar process about the teeth.

It is true that fusiform bacilli and spirochetes may be found in pockets surrounding third molars, as described but this does in no full measure explain the securing of continued positive Vincent's smears from the remaining portions of the gums and gingivae of the patient in question.

LEWIS FOX, D.D.S., South Norwalk, Conn.

To the Editor—May I offer a criticism of your reply to a query signed M.D. Connecticut relative to Vincent's angina?

1 The onset need not be rapid but may well be extremely slow and then may result in an acute exacerbation with superficial or deep necrosis of gums, tonsils, tongue or oral mucosa. This stage may follow weeks of very mild tissue infection. 2 There is not always a fetid odor. The odor may be scarcely noticeable and depends on the stage of the disease and on the degree of cleanliness achieved. 3 There is not necessarily an increased flow of saliva. 4 The temperature may not be above 99 in the subacute or chronic cases or it may range to 105 depending on the severity of the infection and the tissues involved. 5 There is not necessarily extreme malaise, weakness and depression. These symptoms vary tremendously. 6 I have never seen mental depressions or a pronounced symptom in any case.

I have seen scores of chronic and subacute infections preceding and following the acute infection. I agree that the presence of fusiform bacilli and spirochetes do not make a certain diagnosis of Vincent's infection but one learns to diagnose these lesions clinically. The absence of spirochetes and fusiform bacilli in repeated smears may be of definite negative evidence.

Your concluding sentence stating that intravenous injection of neoarsphenamine has never been justified in the treatment of Vincent's

infection either theoretically or clinically and has been generally discarded by the practitioners most experienced in the study and treatment of the infection is especially controversial. I treated more than 400 patients in one acute outbreak and have treated scores of sporadic cases since. Not only was intravenous neoarsphenamine or sulpharsphenamine the only successful method of treatment but there was excellent clinical evidence that it was truly specific. I am enclosing two papers on the subject. Since these papers were written I have seen further clinical proof of the efficacy of intravenous arsphenamine. For example a patient with an acute tonsillitis apparently due to Vincent's infection improved spontaneously after having a temperature of 103 each afternoon for a week. Smears were positive. Instead of entirely clearing up the tonsils remained reddened the crypts showing a dirty grayish yellow exudate and the temperature running to 99.6 or 100 F. for another ten days. As in all previous cases there was complete resolution normal temperature and no further sore throat within forty eight hours after the first injection of neoarsphenamine.

I believe the theory that first prompted the use of one of the arsphenamines in these infections was based on the fact that a spirochete is present as a causative organism in Vincent's angina as it is in syphilis and in African sleeping sickness. Therefore it was reasonable to hope that a similar arsenical would be as nearly specific in Vincent's infection as in syphilis. My experience seems to bear out this theory.

H. J. HARRIS, M.D. Westport on Lake Champlain, N. Y.

ANSWER.—About thirty years ago Dr. Thomas L. Gilmer described the condition in the mouth which he called an acute ulcerative gingivitis. He and the pathologist for St. Luke's Hospital, Chicago, studied the condition and found that it was caused by symbiotic action of fusiform and spirochetal organisms. During the war this condition was common among the soldiers and was called trench mouth. Following the war it was almost epidemic in some places, notably during and after the influenza epidemic. The etiologic relation of fusiform and spirochetal organisms in this condition became well known in both the medical and the dental profession but spirochetal and fusiform organisms are almost universally recoverable from inflammatory and ulcerative conditions in the gingival pockets, although the symptoms are entirely different from those of acute ulcerative gingivitis. As the practice of making smears and staining for bacteria in such cases has increased in the last few years, the presence of these organisms has been assumed to imply and has been called Vincent's infection, whereas probably the organisms are not related to the etiology of the condition, at least, no satisfactory evidence of such relationship has been made. The condition is given importance in the mind of the patient and treatment is more rigorously executed when the patient is told that he has trench mouth. An early piece of work on this subject was *Acute Ulcerous Gingivitis*, by Thomas L. Gilmer (*Dental Review* 20 459, 1906). Probably the most authoritative work on this subject is *Oral Spirochetes and Related Organisms in Fusio-Spirochetal Disease*, by David T. Smith, M.S., associate professor of medicine, Duke University School of Medicine, Durham, N. C., published in 1932 by The Williams and Wilkins Company, Baltimore.

Cases of acute ulcerous gingivitis or stomatitis may be divided into two groups: those which are superficial and of easy access—lesions about the teeth, the buccal mucosa and the tongue—and those which are deep and therefore inaccessible—the tonsils and throat. During the World War, the most popular treatment for "trench mouth" was arsphenamine dissolved in glycerin and applied locally. Gradually this has given way to the more simple and less expensive remedies, such as solution of potassium arsenite, solution of sodium perborate, hydrogen dioxide, 5 per cent chromic acid, and "acrioviolet" (a mixture of acriflavine and gentian violet, equal parts). Thorough irrigation with physiologic solution of sodium chloride or iodosaline solution to remove the necrotic material may be followed by the application of alkalinized solution of hydrogen dioxide and finally by painting the area with compound tincture of benzoin. This is a slight modification of the treatment first recommended by Thomas L. Gilmer (*Dental Review* 20 459, 1906). With-out exception, the lesions show improvement in twenty-four hours and are completely healed within a few days. When this simple procedure yields such uniform success, there is nothing to recommend a more elaborate plan. In the *Dental Cosmos* (76 329, 1934) the Beldings, in discussing the use of neoarsphenamine and glycerin or solution of potassium arsenite state that if a patient is unable to afford the neoarsphenamine this may be omitted without seriously affecting the spirocheticidal activity.

Cases of acute ulcerous gingivitis sometimes develop while the patient is under antisyphilitic treatment with arsphenamine and mercury. This undoubtedly is explained on the ground that the mercury has increased the amount of gingival irritation and that the spirochetes have become arsenic fast.

When the ulceration involves the tonsillar crypts or is penetrating deep into the pharyngeal walls, local treatment should

be supported by the use of arsenicals. In such cases, intravenous injections of arsphenamine or sulpharsphenamine may be advisable. As is well known, this treatment is not without its untoward effect. It is decidedly unsafe to use the arsphenamine unless one is prepared to meet emergencies.

ALLERGY TO CAT HAIR

To the Editor.—A girl aged 9 years suffering from severe asthmatic attacks most of her life was brought to me by the state bureau of child welfare. I spent several months investigating by means of food proteins and bacterial proteins and even gave her a course of injections of an autogenous mixture. The attacks were not influenced much. The history gives no clue as to seasonal influences. It was only when I tried to test her with epidermal extracts that I found that cat gave her a definite skin reaction with pseudopods. She lives in the country and though she has had no cat in her house for several years there is an indefinite history that cat might be the cause. Owing to the fact that she lives quite a distance from my office and that it is considerable trouble to bring her in regularly for treatment, and also because the child is being treated without any remuneration I should like to hear an expression of the possibilities of her being cured by desensitization with protein extracts from cat epidermis before giving the treatment. Owing to the severe nature of the attacks when they come I would appreciate an early response. Please omit name.

M. D. Connecticut

ANSWER.—It would seem that exposure to cat hair might be the precipitating factor in this child's attacks of bronchial asthma. Cat hair is a common cause of such spells, more common than is the hair of dogs, a positive test to cat hair usually means that the patient is clinically hypersensitive to cat hair.

Cat hair is frequently encountered when there is no direct exposure to cats.

Coca in his book (*Asthma and Hay Fever*, by Coca, Walzer and Thommen) writes as follows:

Pelts of the domestic cat (*Felis domestica*) are gradually assuming importance as furs. The skins are dressed dyed to imitate other furs and sold under names suggestive of more costly skins to be used for those purposes for which genuine furs are employed.

Cat skins are commonly used for making carriage robes and for lining caps coats gloves slippers etc.

Cat hair is employed as a covering for toy animals and as an adulterant of hair stuffing bedding and furniture.

Other members of the cat family also supply furs. Chief among these are leopard (*Felis pardus*) panther (*F. panthera*) wild cat (*F. catus*) jaguar (*F. onca*) tiger (*F. tigris*) lion (*F. leo*) and the lynx (*F. lynx*). The latter is also known as the caracul or Persian lynx (*Felis or Lynx caracul*). This is to be distinguished from Karakul which is Astrakhan obtained from the pelts of young lambs.

Civet cheetah and genet are also members of this family.

Desensitization can be readily accomplished by a series of injections. It is usually sufficient to begin with 0.02 cc. of a 1:100,000 dilution, although if the patient is extremely hypersensitive it may be well to begin with a 1:1,000,000 or even a 1:10,000,000 dilution. Injections are to be given subcutaneously about twice a week, with increases (if no severe local or if no general reaction occurs) of about 50 per cent for each dose. The final dosage has not been definitely agreed on but probably 0.10 cc. of a 1:100 dilution is high enough.

There is considerable controversy among allergists as to the advisability or necessity of such desensitization. Elimination of cats and products made from cat hair is usually sufficient. However if exposure is unavoidable and if contact with cats brings on attacks of asthma, desensitization is definitely indicated and should be carried out. The result of such a series of injections is usually a success.

The material for the treatment can be purchased from several pharmaceutical houses.

USE OF NEOARSPHENAMINE IN VINCENT'S INFECTION

To the Editor.—In *Queries and Minor Notes* in *THE JOURNAL*, February 24, p. 640 the statement is made that intravenous injection of neoarsphenamine has never been justified in the treatment of Vincent's infection either theoretically or clinically and has been generally discarded by the practitioners most experienced in the study and treatment of the infection. Please explain in detail the treatment of this disease today also explain why this statement is made in the face of clinical evidence that the condition does clear up following the use of the arsenical. What is done in Vincent's infection of the lung. I know there have been two schools of argument but I think your statement is strong. Please give me the proof.

G. R. CLAYTON, Lafayette, Ind.

ANSWER.—The statement "intravenous injection of neoarsphenamine has never been justified in the treatment of Vincent's infection either theoretically or clinically" taken by itself and separated from the context, cannot be supported. The answer to the previous question spoke only of the treatment of acute ulcerative gingivitis which has been more or less improperly called Vincent's infection. The statements made in regard to

the treatment of acute ulcerative gingivitis obviously would not apply to Vincent's infection of the lung. The statement quoted in the query is based on the following facts. In acute ulcerative gingivitis a mixed culture attacks local areas of surface, producing rapid surface ulceration and necrosis. The bacteria do not penetrate deeply into the tissues. Theoretically, therefore, attack from the surface would be expected to be more effective than to attempt to reach the bacteria through drugs introduced into the blood stream. Clinically, this condition not infrequently develops in patients on treatment with neosarsphenamine. Next, under direct local attack, conditions improve within twenty-four hours and always clear up promptly without the use of intravenous injections. The essentials of treatment of acute ulcerative gingivitis are cleansing of the surfaces and removal of the membrane, and frequent application of substances that liberate oxygen, such as sodium perborate, hydrogen dioxide, 5 per cent chloric acid, or a mixture of acriflavine and gentian violet. The areas may be protected by painting with compound tincture of benzoin. When the areas attacked can be reached, they always yield rapidly to this treatment.

NONALLERGIC COSMETICS

To the Editor—I have a patient who develops a dermatitis on using any of the common foundation and cleansing creams such as DuBarry Max Factor or Madame White. I should like to know what I can recommend to this patient as a beauty preparation and also what is the irritating factor in these creams. Please omit name.

M D, North Dakota

ANSWER—There are several companies manufacturing lines of cosmetics that are not irritating to the large majority of individuals. Most of such preparations are free fromorris root, rice, lead, mercury and other chemicals that might be irritating to the skin.

Orris root, which is the rhizome of *Iris germanica*, *Iris pallida* and *Iris florentina*, has a pink flesh tint and a delicate odor of violets. It is widely used in the preparation of various kinds of cosmetics, including many foundation and cleansing creams. It is one of the main causes of dermatitis in individuals who are sensitive to it.

Among the preparations that may be recommended are the Marcelle products manufactured by C W Beggs Sons & Company, 1741 North Western Avenue, Chicago; Macauley preparations, made by Macauley Laboratories, P O Box 6 Flatbush Station, Brooklyn; the Mansfield preparations of E R Mansfield Company, Ltd, Los Angeles; Frost's preparations, produced by Frost's, Memphis, Tenn; and Non-Allergic Products, manufactured in St Louis.

DETECTION OF AMEBAS IN STOOLS

To the Editor—In a small town where there is no laboratory, only the study of fresh, warm stool specimens is possible for amebas. The method of Riparte and Petit as outlined for concentration is practical, but is there not an easier way to fix and stain for visualization of amebic cysts than by the hematoxylin method? If so outline. Kindly omit name.

M D California

ANSWER—The iron-hematoxylin method of staining amebas and their cysts is still the most reliable in spite of its time-consuming tediousness and the skill or luck required in its successful application. The iodine method is simple and is adequate for most purposes. A small drop of fecal emulsion and an equal drop of iodine solution (5 per cent iodine in 10 per cent potassium iodide) are placed on a slide and covered with a No 1 cover glass. This technic reveals the internal structure of trophozoites and cysts adequately for diagnosis in most cases. It is frequently not satisfactory in the examination of cultures in which the active amebas may have taken up many starch granules.

Two other methods have been employed with success by some workers.

1 Modified Mallory's phosphotungstic acid hematoxylin. This stain is prepared as follows:

Solution A	Hematoxylin (white crystals preferred)	0.2 Gm
	Distilled water	160 cc
	Dissolve by boiling	
Solution B	Phosphotungstic acid	10 Gm
	Distilled water	100 cc
	Dissolve by boiling	

When cool mix 80 cc of solution A with 20 cc of solution B. Allow the mixture to ripen for from one to five months in a covered, not stoppered, bottle in the sun if possible. The ripening can be hastened by the addition of a drop or two of hydrogen dioxide.

Smears of optimal thickness from the specimen of feces are placed while still moist in warm (37 C) Schaudinn's solution for from five to ten minutes.

Rinse in two or three changes of distilled water.

Place in the stain in a Coplin or other jar for from one to twenty-four hours. If the jar and stain are kept at incubator temperature, satisfactory results may be obtained by staining for from one to three hours.

Rinse in two or three changes of distilled water.

Place the slides for a few minutes successively in 50 per cent, 75 per cent and 85 per cent alcohol, then into 95 per cent and absolute alcohol for ten minutes each.

Clear in xylene and then on clove oil for from five to ten minutes each.

Blot, and mount in neutral balsam.

2 Recently a new method has been described by H E McDaniels (*Science* 79 187 [Feb 23] 1934).

To a drop of an emulsion of feces a drop of a saturated solution in methylene blue in methyl alcohol is added on a slide. This is covered with a No 1 cover glass. "All fecal remains, with the exception of certain crystals, are stained dark blue and thereby merged with the rest of the dark blue field. The whole preparation may be searched with the low power objective in a very short time. Examination with the 4 mm or oil immersion lens will show the nuclear chromatin of the amebae and cysts to be selectively stained with the methylene blue. Trophozoites are rounded up by contact with the methyl alcohol, but the nuclei may be seen distinctly, even in the presence of much ingested material. The only precautions to be observed are to reduce the amount of light and to make thin preparations, either use small drops of fecal emulsion and staining solution, or use large cover slips to spread the mixture over a larger area."

DIABETES MELLITUS OR RENAL DIABETES

To the Editor—I am writing you for your valued opinion of the case of a colleague in whom I am deeply interested and in whose case it seems to be certain points that make the diagnosis obscure. The discovery of sugar in the urine was made about two months ago by an insurance examiner and though there are no subjective symptoms of diabetes he continues to show sugar in definite quantities on ingestion of only moderate amounts of carbohydrates. His sugar tolerance after 50 Gm of sucrose is as follows:

	Blood Sugar Mg per 100 Cc.	Urine (Reduce to 100 cc Benedict's Solution)
1 12 hours fasting stomach	100	Negative
2 15 minutes after intake	125	
3 30 minutes after intake	182	Very slight
4 45 minutes after intake	167	
5 1 hour after intake	150	Definite
6 2 hours after intake	105	Very slight
7 3 hours after intake		Negative

The patient is 56 years of age. His height is 5 feet 6 inches (172.7 cm.), his normal weight 137 pounds (62 Kg.) he is well nourished and the past history is irrelevant. His daily regimen has recently changed in that he has been obliged to drive his car 25 miles to and from his office and there seems to enter the factor of worry incidental to his personal affairs. The question arises as to this being a true diabetes mellitus or the making of one of renal origin. Please omit name.

M D Florida

ANSWER—It is difficult to make the differential diagnosis between diabetes mellitus and renal diabetes from the data furnished. The fact that, in this case, glycosuria is definitely associated with alimentation might be taken to favor the diagnosis of diabetes mellitus rather than a glycosuria of renal origin. However, the rule that renal diabetes is characterized by a lack of relationship between alimentation and glycosuria holds only in moderate or severe cases, i e, when the renal threshold is considerably lowered. It is evident from the blood sugar curve cited that such is not the case here. At a blood sugar level of 182 mg per hundred cubic centimeters the urine test was only "very slight." The fact that a "definite" urine sugar test was obtained as the blood sugar level fell toward 150 mg may be due to the fact that the blood sugar level continued to rise for a short while before starting to drop.

From the high normal initial blood sugar level, from the fact that the blood sugar rose to a rather high peak and barely returned to the original level within two hours, and considering the probability that the renal threshold was not depressed the diagnosis of the condition is a mild or early diabetes mellitus. However, the mention of a recently changed daily regimen and of worry incidental to personal affairs is important. Certain cases of mild hyperthyroidism may show changes in carbohydrate metabolism similar to those described. These changes are hardly distinguishable from those of uncomplicated diabetes mellitus, except for the presence of the symptoms usually associated with disturbances of the thyroid gland. It would therefore be well to examine the patient with this possibility in mind.

It is also suggested that a repetition of the carbohydrate tolerance test using 100 Gm of sugar instead of 50 Gm, would furnish a result of greater diagnostic significance.

WRITINGS OF PHYSICIST MILLIKAN

To the Editor—In one of the editorials in *THE JOURNAL*, January 20 a quotation was given from an American physicist R A Millikan. Kindly let me know more of the writings of this man. Has he published any of his works? What are they? Where did you find this quotation?

THOMAS ST CLAIR, MD Latrobe Pa

ANSWER—Prof Robert A Millikan is at present the director of the Norman Bridge Laboratory of Physics, and chairman of the Executive Council, of the California Institute of Technology at Pasadena. Previous to his transfer to California in 1921 he was professor of physics at the University of Chicago. He is one of America's most distinguished students in this field, having received the Nobel prize from the Royal Swedish Academy in 1923 for his studies on the electron. Dr Millikan has written extensively on the relations of science to modern life and likewise on the possible interrelations of science and religion. At the present time he is active in the study of the cosmic rays.

The quotation to which our correspondent refers (in an editorial on "The Social Order and Human Health," *THE JOURNAL*, January 20, p 215) was taken from Harris, F S, and Butt, N I *Scientific Research and Human Welfare*, New York, Macmillan Company, 1924, page 4.

Many of the more popular lectures of Dr Millikan have been published in *Science* and similar magazines. A partial list of his writings includes

- 'A Scientist Confesses His Faith' Chicago 1923
- 'Suicidal Nationalism' California Institute of Technology bulletin 1924
- 'Science and Life' Pilgrim Press 1924
- 'Evolution of Twentieth Century Physics' Annual Reports Smithsonian Institution 1927 pp 191-199
- 'Science and the New Civilization' New York Charles Scribner's Sons 1930
- 'Radio's Past and Future' University of Chicago Press 1931
- 'Time Matter and Values' University of North Carolina Press 1932
- 'Science and Modern Life' in *The Creative Intelligence in Modern Life* University of Colorado semicentennial series vol V
- 'Evolution in Science and Religion' New Haven Conn, Yale University Press

BRAIN TUMOR OR PSEUDO UREMIA

To the Editor—A white man aged 32 has severe headache (worse in the morning) dizziness and vomiting. The vomiting has been projectile on two occasions but is always preceded by nausea. He is a coal man and has done heavy shoveling riding on a rough truck and frequently works while his feet are wet. The sinuses and teeth are normal. The entire physical examination is negative except for loss of the plantar reflex, loss of the lower abdominal reflex, a marked Romberg sign and the fact that both optic disks are under slight pressure, the left more marked (2 diopters) with its medial margin blurred. The headache is described as arising low in the occiput and extending along the right side to the frontal region. During the past ten days the headache has been in the frontal area. The Widal test is negative, the blood Wassermann and spinal fluid Wassermann reactions are negative (spinal fluid under negligible pressure). A blood urea nitrogen test returned 64 mg per hundred cubic centimeters. There is a trace of albumin in the urine with two coarse granular casts to a field. The patient was put on digitalis, potassium citrate and a protein-free diet and in three days the blood urea was down to 8 Gm. Comfort for two or three days was followed by violent occipital and frontal headache and dizziness. The blood urea nitrogen this time was 9 mg. The patient was now put on a regular (rather high protein) diet and after four days of this the blood urea was 15 mg. During this period he would have two or three days of comfort followed by violent headache, dizziness and occasional nonprojectile vomiting. No increase in pressure was shown by the optic disks. For the past ten days the patient has been on a low protein diet from 800 to 1000 cc of water daily and potassium citrate. He has had no violent headache, only slight dizziness and no vomiting. He sits up one hour each day but every other day complains of a slight frontal headache. Throughout his illness his pulse rate has remained between 74 and 82. The blood pressure is 120 systolic 65 diastolic. The temperature ranges between 98.4 and 98.8. Frequent attacks of hiccup still persist. No localizing signs relative to brain tumor can be picked up. Would you kindly tell me the prognosis in this case? Is this now pseudo uremia? Can anything particular in line of treatment be done? Please omit name.

MD Pennsylvania

ANSWER—From the data presented one must conclude that this is almost certainly not a case of pseudo-uremia but one presenting evidence of local intracranial disease quite probably of a neoplastic nature. The apparently abrupt onset with projectile vomiting and vertigo and the disturbed reflexes are significant. A papilledema of 2 diopters must be considered decidedly more than evidence of slight pressure and the asymmetry of the degree of disk choking speaks for local intracranial disease. The negative spinal fluid Wassermann reaction makes syphilis of the central nervous system highly unlikely, although not truly impossible. An increase in the content of the blood of urea nitrogen is not uncommon in instances of brain tumor, particularly when there has been much vomiting with subsequent dehydration. The perfectly normal arterial

tension with normal cardiac efficiency excludes any diagnosis of uremic or azotemic intoxication. It is hard to grasp the logic of the digitalis therapy, as no evidence of cardiac inadequacy was mentioned in the query. It is felt that the low protein diet, the digitalization, and the restriction of the fluid intake are not warranted by the reported observations. Remission of the intensity of symptoms is not infrequent in intracranial neoplastic disease, it is unjustifiable to assume that the transient improvement noted is necessarily attributable to the therapy instituted. The following suggestions appear appropriate from the data presented: 1 Further extensive neurologic studies, including careful mapping of possible areas of disturbed sensation, outlining the visual fields and, further, more exact studies of the spinal fluid pressure. 2 A liberal food and fluid intake. An increase in fluid intake is indicated all the more when azotemic retention occurs. The diagnosis and localization of brain neoplasms frequently tax the skill and ingenuity of the neurologist to the utmost.

EDEMA OF FEET IN TUBERCULOSIS

To the Editor—I have been a specialist in tuberculosis many years and I am seeking information concerning a certain condition about which there is practically nothing in the literature. The condition is the gradual onset of edema on the feet later accompanied by dyspnea and always proving fatal within a few months after onset. It is unaccompanied by fever or rapid pulse and while of course it is common in terminal cases I have seen it in moderately advanced cases in persons up and about often working. It usually is unaccompanied by any renal condition or cardiac condition. Of course in the approaching terminal cases there probably is a high grade of myocarditis from the long continued toxemia but from my own observation it is not a manifestation of either cardiac or renal disease in many cases. And I should like to know the cause of this symptom complex. Of course one can generalize and theorize and say it is a manifestation of toxemia but against that it usually occurs in those who are quiescent as regards their pulmonary tuberculosis. I have tried repeatedly full cardiac stimulation and diuresis but the course of the trouble is apparently uninfluenced by any medication. I have also tried intensive calcium therapy on the theory of undue liquefaction of the blood plasma also without effect. Also the urinary output is usually normal in quantity as well as quality. A salt free diet and limited fluid intake are also without results. In fact every one of these patients has died in spite of every effort. Therefore I am anxious to have some explanation of this symptom complex and of course some efficient type of treatment to overcome it. In conclusion I will say that while practicing in low altitudes I do not remember seeing this symptom complex. The altitude here is 6000 feet.

DAVID KRAMER MD Silver City N M

ANSWER—Like many other questions on edema, this one is difficult to answer. The type reported here appears to be a new observation.

Edema is due to faulty water exchange in the body, and this may in turn be due to several causes. A derangement of the organs that have to do with the movement of body water leads to edema. An insufficient heart may lead to "cardiac edema," and a derangement of the kidney to either nephritic or nephrotic edema. In addition, a long standing malnutrition or an interference with the brain stem may lead to edema. There is no theory, however, that can explain all aspects of edema from Starling's theory of the change of intravascular osmotic pressure to the chemical theory or to the derangement of a hypothetical nerve center. No doubt, changed osmotic pressure plays a part when other factors are present, no doubt, the change in ionic constellations or a colloid state within the cell is important. Perhaps there are central nervous system centers that through stimulation or suppression may lead to an interference with water movement that may result in edema. Yet none are altogether sufficient. It is possible that several factors operate in series aided by vicious cycles that almost always result.

For example, a gradually weakening heart will proportionately slow down water movement until the water depots (skin muscles, liver and spleen) become saturated and overflow into the tissue spaces. This will also tend to decrease oxidation in the water depots which in turn will change the ion constellations in the cells of these tissues. This will decrease the ability of the cell to hold water so that progressive syneresis or a giving up of the water by colloids is the result. The same may be said concerning edema of nephritis and particularly nephrosis in which the depletion of albumin leads to a lowering of osmotic pressure in the blood and a retention of water in the cells to the point of supersaturation when free water appears in the tissue spaces. Nor can it be denied that a nerve impulse from a nerve center in the brain may also increase or decrease the water holding power of the cells.

How then may these various possibilities bear on the problem presented? It is obvious that the condition is not one of the common forms of edema. It is apparently not even the terminal

edema occurring in tuberculous individuals. The two common factors in the problem presented appear to be chronic fibroid tuberculosis and high altitude. This would lead one to suspect that a decreasing oxidation within the cells may be a contributing factor.

The toxemia of the disease, added to the decreased power of oxidation within the cells, results in a changing ionic balance and a change in colloid stability. In addition, a low oxygen tension necessitating increased pulmonary ventilation in the presence of a diminished alveolar surface from diseased tissue or the emphysema of healing may in combination lead to such an intractable condition. As a suggestion, it may be useful to test the effect of high oxygen tensions on such patients. Irrespective of any apparent benefits from such a procedure there is little hope of a permanent recovery, as the body reserves have apparently become physiologically bankrupt.

USE OF OLIVE OIL IN GASTROINTESTINAL DISEASE

To the Editor—A patient of mine, aged 21 who three years ago because of epigastric discomfort, pyrosis and eructations, was ordered by her doctor to leave meat out of her dietary and to use olive oil freely. She has had occasional remissions of trouble in the interval. During the past six weeks her complaint has been of mild frigate eructations of gas with associated sourness and mild gastric discomfort. There is also a sense of what the patient calls spasm in the upper half of the abdomen occurring after stool. A fractional analysis has not been done. My diagnosis is (1) chronic peptic ulcer and (2) gastric stasis with fermentation the second condition being due to the oil. The questions I ask are: 1. What is the use of olive oil other than (a) as a cholagogue (b) to inhibit the rate of gastric secretion and (c) as a lubricant? 2. Is olive oil a food? 3. If so what is its metabolism and its waste product (passed with the feces) in the human being? 4. Does olive oil cause frequent eructations? I advised the patient to diminish her daily quantity of oil and to take fig and bran flakes if costive. Please omit name. M D, Canada

ANSWER—The evidence presented is insufficient to justify a diagnosis of chronic peptic ulcer or gastric stasis with fermentation, the latter in particular without a gastric analysis.

1. It should be remembered that massive doses of olive oil taken for its cholagogue effect not infrequently result in the passage of masses of fatty acids that the patient may believe are calculi. Certain alleged cures for gallstone sold as "patent medicines" are essentially olive oil and a saline which bring about the passage of soapy concretions that the victim thinks are gallstones.

2. Olive oil is a food, not a lubricant.

3. Olive oil is digested in the gastrointestinal tract like any other fat. If given in excess in the presence of a pancreatic disease in which fat digestion may be interfered with, or when the intestinal contents are hurried through with unusual rapidity, fat may appear in the stool. Otherwise no fat will be found in the stool.

4. Ordinarily not. Eructations may occur in any gastrointestinal complaint.

INTESTINAL MYIASIS

To the Editor—I have a patient under observation for the following condition which apparently has been very resistant to all forms of treatment and until I received the laboratory report the exact trouble was not known. She had been treated for years for worms. Her husband brought to my office what appeared to be worms but which the laboratory diagnosed as larvae of the common housefly and the laboratory workers had to wait until they came out of the pupal stage before the diagnosis could be made. Apparently the patient has an enormous number of these in the intestinal tract and is no doubt, an incubator for them. Not finding any form of treatment in any of the textbooks on this condition I would appreciate it if you would outline a treatment that would rid this patient of her complaint.

A. P. KIMBALL, M.D., Yuma, Ariz.

ANSWER—Myiasis is the term applied to a disease condition resulting from the occurrence of the larvae of flies of different species in the intestinal and urinary tracts. Among the species most generally responsible, according to Hewitt is *Musca domestica*, the housefly.

When the larvae are present in the stomach they may cause violent pains and dizziness and are often expelled by vomiting. In the intestine they give rise to abdominal pains and diarrhea not infrequently accompanied by hemorrhage caused by the larvae perforating the mucous lining of the intestine. Occurrence of the larvae in the urinary tract is more remarkable but cases have been on record since the seventeenth century.

Hewitt suggests several methods of infestation. All the flies are attracted to decaying animal or vegetable products, excrementous or purulent substances, for the purpose of depositing their eggs. Should these eggs be on food, the eggs or young larvae would be taken into the digestive tract. Intestinal infection may result from the flies, which frequent privies for the

purpose of ovipositing, depositing their eggs in the anal region, and the larvae on hatching enter by way of the rectum. Infection of the urinary tract is more difficult to understand, especially in the case of the male. Flies would be attracted to the genital apertures by the various albuminous and other secretions, especially in cases in which the organ is exposed for any length of time.

Treatment does not seem to have much effect, for the larvae leave of their own accord, through the anus, when approaching maturity. The usual vermifuges, such as santonin, pepo, oil of chenopodium or thymol, are of little value, but mild purgatives and high enemas may hasten their departure.

PREGNANCY IN WOMAN OF FORTY-FIVE

To the Editor—I have a patient aged 45 who was normally delivered of a living child eighteen years ago. She had two therapeutic abortions twelve and six years ago because of acute toxemia of pregnancy and at present has a delayed menstrual period not long enough for a urine test. To handle the case properly if there is a pregnancy I should like to know how frequently a pregnancy occurs at this age under similar circumstances what its average course is and the most advisable and also average procedure in delivery. Please omit name. M D, California.

ANSWER—These questions cannot be answered satisfactorily, even in a general way because not enough data have been supplied and because there is great difference of opinion on the subjects mentioned.

In the first place, the question of pregnancy must be settled. Secondly, if there is a pregnancy, no one can quote statistics as to its frequency under such circumstances. Pregnancy is rare at the age of 45 in healthy women and much more uncommon in women with chronic nephritis. It seems that this woman suffers from a latent chronic nephritis or what some authors call a low reserve kidney. As regards the average course of such a case, one cannot generalize. The pregnancy would in all likelihood aggravate the kidney disease and the kidney disease would more than likely produce a late abortion or abruptio placentae.

As regards the "average procedure" in delivery, only general rules apply. In the presence of threatening eclampsia the uterus should be emptied and, in any event, if the woman should be carried to the point of viability of the child, emptying the uterus ought to be considered.

The questioner is referred to the recent works of Dr. H. J. Stander and Dr. C. H. Peckham, and Dr. E. J. Stegitz's *Arterial Hypertension*, chapter on its obstetric aspects.

BRACHIAL PLEXUS NEURALGIA

To the Editor—I have recently seen a woman aged 24 who suffered with what appeared to be a brachial plexus neuralgia. Her general health is good and previously she was entirely well except for the neuralgic pain in the arm. She suffered her first attack of this trouble at about 10 years of age following measles. Since that time she has had one or two attacks each year. These have never been severe enough nor persisted long enough to require medical attention. Her recent attack began with an aching pain which lasted for two or three minutes and originated in the upper part of the arm and extended to include the entire arm and hand. There was an interval of four or five hours without pain. The attacks then recurred with gradually increasing severity and a shortening of the intervals between them until they occurred at intervals of from thirty minutes to one hour with the pain persisting for from fifteen to twenty minutes. The pain is described as that characteristic of trifacial tic, viz. excruciating lightning-like pain shooting through the right arm. The pain was so severe that she blistered the hand and lower arm in holding it before an open fire. She was surprised to find that she had produced this burn stating that the pain was so severe that she had not been able to feel the heat from the fire. There is no radiation of the pain along the long thoracic nerve or the radial subscapularis. There is no herpes or selectivity to either the lacerated ulnar or median and an absence of pain or soreness during the lull interval. I have not been able to find a report of such an attack of tic occurring as a brachial plexus neuralgia. I had occasion to ask a neurologist about the condition and he stated that he had not seen or read a report of such a case. I should like to know whether similar cases have been reported and what treatment might be offered in relieving these attacks should they recur.

ROY E. EMANUEL, M.D., Chickasha, Okla.

ANSWER—One is left by the correspondent to suppose many things particularly that careful examination was made and no evidence of organic disease was found. Lightning pains in the arms may be present in several disorders, such as proliferative osteoarthritis in the cervical region, syringomyelia, cervical pachymeningitis, and intraspinal tumor. In this particular case one might suspect syringomyelia because of the history of burning the hands without knowing it. No malady similar to trigeminal neuralgia, affecting the brachial plexus, has been distinguished.

Book Notices

Thirty First Annual Report 1932 1933 of the Imperial Cancer Research
Fund Under the Direction of the Royal College of Physicians of London
and the Royal College of Surgeons of England November 1933 Paper
Pp 19 London 1933

Studies made by Mr Crabtree and Dr Cramer on the action
of radium on cancer cells have elicited some interesting facts
related to radiosensitivity. Two methods were adopted. 1
Thin slices of tumor tissue were exposed to radium and various
inhibitors of metabolism and the amount of respiration and
aerobic glycolysis were recorded. 2 Tumor tissues that had
been exposed to the inhibiting solutions were transplanted and
their behavior was noted. It was established that hydrocyanic
acid inhibits respiration specifically but does not inhibit gly-
colysis. Transplantability and growth are not at all affected
even by exposure to a concentration of twentieth molar hydro-
cyanic acid for one hour at 37 C. Iodo-acetic acid and sodium
fluoride were found to have a definitely toxic action on the
living cell. After the appropriate concentration from which
complete recovery is possible had been established for these
various inhibitors of metabolism, the effect of radiation was
studied on tumor cells in which either glycolysis or respiration
was in abeyance. Other methods of arresting respiration are
by the withdrawal of oxygen (anaerobiosis) and by exposure
to cold. Experiments were devised in which radium radiation
was applied to tumor tissue while either respiratory or aerobic
glycolysis was profoundly modified. It was found that exposure
to hydrocyanic acid and to low temperature greatly increases
the susceptibility to radium. Anaerobiosis produces the opposite
effect, greatly increased resistance. Since both hydrocyanic
acid and anaerobiosis produce increased glycolysis and the effect
produced on radiosensitivity is in opposite directions it is con-

cluded that the biologic effect of radiation is not produced
through an action on the glycolytic mechanism. This is con-
firmed by the fact that iodoacetic acid and sodium fluoride
which inhibit primary glycolysis do not influence the effect of
radiation. These experiments suggest that the lethal action of
radiation on living cells is due to its action on the respiratory
mechanism. The authors believe that the problem of radio-
sensitivity of cancer cells is the resultant of a considerable
number of largely independent factors. It is also suggested that
local conditions of impaired vascularization may set up a degree
of anaerobiosis that influences susceptibility to radiation. Dr
Ludford's experiments utilizing vital staining by trypan blue
permitted a clear distinction to be made between the tumor
cells—carcinoma and sarcoma—that do not segregate the dye
and the nonmalignant associated cells that do. Further experi-
ments with other tumors of the mouse and rat have shown
that the distinction between normal and malignant cells by
these methods is not absolute but is, in part, an individual
peculiarity of the strain of tumor employed. Dr Watson has
studied the effects of adding fresh ox or horse liver to the diet
on tar carcinogenesis in mice. He found that a greater propor-
tion of the animals develop tar tumors and that they appear
earlier than in the control series. The studies discussed in
this report are of special interest and the results suggest
further avenues of approach in the effort to gain a deeper
knowledge of the factors underlying tumor growth. The inves-
tigations on radiosensitivity are particularly welcomed because
of the lack of understanding of the factors that determine sensi-
tivity and resistance to radiation.

The Nature and Treatment of Amentia. Psychoanalysis and Mental
Arrest in Relation to the Science of Intelligence. By L Pierce Clark,
Chief of Advisory Board of Research of Letchworth Village for Feeble-
minded. Assisted by the Staff of the Psychoanalytic Sonatorium of NYC.
N Y T E Uniker Ethel L Rourke W K Cushing and Margaret C
Calms. Foreword by Ernest Jones MD President of the International
Psychoanalytical Association. Cloth Price \$4.25 Pp 306 Baltimore
Willom Wood & Company 1933

Special recreational work and carefully developed educational
technics have already proved that feeble-minded persons can be
made to appear more adequate than was formerly considered to
be the case. There is no reason why technics, such as psycho-
analysis, should not be brought into this field to aid in the
adjustment of these classes of patients, and the thesis of
Dr Clark is that the application of the freudian methodology
does aid the feeble-minded child in making better adjustments to
society and assists him in leading a more contented life. There
is much discussion of the technics and mechanisms involved in
this work but significant features are those presented in the
discussion of eleven illustrative case studies, which take up a
large portion of the book. It must be admitted that these cases
are interesting and show that the children did make progress.
Because the cases were specially selected, there remains in the
mind of the reader the impression that now a technic has been
found that will prove significant in the handling of feeble-
mindedness, but because of the same fact that these are specially
selected cases some doubt is cast on the usefulness of an unvary-
ing application of the freudian method, although the author
does select his cases from among all of the various types of
feeble-mindedness. This volume can be considered only an
interesting preliminary report, and much more work will have to
be done before the analytic technic can be proved to have an
important place in the field of treatment for feeble-minded
patients. The bibliography is inadequate and the author is prone
to use such archaic terms as 'amentia' and 'mental arrest'
which were long since discarded by the meticulous psychologist.

Mikroskope und Chemie am Krankenbett. Von Hermann Lenhartz.
Fortgeführt von Erich Meyer. Ffventh edition revised by A V Domarus
and R Seyderhelm. Paper. Price 18 60 marks. Pp 370 with 182
illustrations. Berlin Julius Springer 1934

The high standard of this compact manual of laboratory
technic familiar to every German speaking physician has been
maintained in the present edition by careful revision and incor-
poration of the most popular newer laboratory methods such
as vital stain for reticulocytes, oxidase reaction, examination
of blood in a thick drop according to von Schilling's method,
determination of sedimentation rate and various micromethods.
The small volume covers in a concise, comprehensive manner

the field of the routine laboratory technic. The illustrations are instructive and the colored plates beautifully reproduced. Few omissions have been noticed. In the etiology of gas edema, *Bacillus perfringens* and the septic vibrio have not been mentioned. Only Lundsteiner-Moss's classification of blood groups is described, Jansky's being omitted. Himes' sugar test is missing. Among functional liver tests, only the galactose test could be found. No description of the several new methods of examination of gastric contents, such as the alcohol or the histamine test, has been offered. This handy little volume compares favorably with similar manuals in English and can be heartily recommended to all physicians who speak German.

Pathologie und Klinik der Granulosa-Zell-Tumoren. Von Dr. Walter Schiller, Assistent der II. Universitäts-Frauenklinik (Prof. Dr. Wilh. Welbel). In Wien. Cloth. Price 16 marks. Pp. 197, with 131 illustrations. Vienna: Wilhelm Maudrich, 1934.

The histologic interpretation, clinical evaluation, definition and description of granulosa cell tumors of the ovary are full of controversies; hence every gynecologist will welcome a critical review of the literature and detailed description of sixteen benign and eight malignant cases in addition to a report of experiments dealing with production of granulosa cell tumors by means of injections of a hormone combined with application of a carcinogenic agent. On the basis of clinical observations, histologic studies and results of experiments the author discusses the histogenesis of a normal granulosa as well as granulosa cell tumors, arriving at the conclusion that the tumors derive from undifferentiated residues of the mesenchymal nucleus of the ovary. He describes the clinical aspects of such tumors, including the age incidence, importance of ascites, frequency of malignant degeneration, production of hormones by the tumors with resulting hormonal effects such as amenorrhea, menorrhagia, postmenstrual hemorrhages, and feminization or masculinization. The monograph is profusely illustrated and represents the fruit of an exhaustive study of a problem that is not only of theoretical interest but also of great clinical importance.

Clinical Tests of the Function of the Heart. By Gustaf Nylin. Acta medica Scandinavica Supplementum III. Paper. Pp. 92, with 5 illustrations. Helsingfors: Mercator's Tryckeri Aktiebolag, 1933.

This volume consists of a brief review of the literature followed by a report of Nylin's own investigations. Half of the book is made up of a long table of his case material consisting of 143 subjects, some with normal hearts and some with diseased hearts. There is a bibliography of ninety-two references. The author begins by outlining his method of study. For the purpose of studying the effect of graduated work a special staircase was constructed, made in four sections and running in a circle when put together. Every section consisted of six steps. The total height of the staircase was 1 meter, so that every person experimented on had to raise and lower the weight of his body twice alternately during one round of the stairs. Even in severe decompensation cases Nylin found a rate of 88 steps per minute suitable, the number of rounds the patient had to make in such cases was five. Healthy persons and patients with slight decompensation had to perform the work at a rate up to 160 steps per minute, the number of rounds varied from five to ten or twenty, the last mentioned being, however, very considerable and suited only to the quite healthy. A rate of 88 steps per minute means that the patient alternately raised and lowered his own body weight 147 meters per minute. In the morning the oxygen consumption of the completely rested subject was determined first for which purpose a Krogh spirometer was used. Then the oxygen consumption was again determined after a fixed amount of work on the stairs timed with a metronome. On the conclusion of the work it usually took about fifteen seconds to fit the Krogh spirometer; the registration began immediately and was continued for varying periods though not less than five minutes after the cessation of work. On all the curves was marked the time during which the oxygen consumption was calculated beginning exactly at the second minute after the cessation of work and stopping exactly at the end of the fifth. In several cases the investigation of the oxygen consumption was continued for a further five to fifteen minutes. In determinations of

the utilization, the author employed Grollman's acetylene method. The investigations of minute volume during rest and after work covered a smaller material than those carried out for oxygen consumption, as the determinations were very slow, and the method was difficult to master. In a large number of cases, among both the healthy and the sick subjects, simultaneously with the investigations of oxygen consumption both during rest and after the cessation of work, determinations were made of the systolic and diastolic blood pressure and the pulse rate. On the basis of these determinations Liljestrand-Zander's product was calculated in the first place during rest and in the second after work of fixed intensity in the time periods mentioned. Then the increase of this product was calculated as a percentage of the resting value.

The results were as follows. Among healthy subjects, cases of heart insufficiency during rest, cases of compensated valvular trouble, myocardial degeneration, hypertonia, and some cases of exophthalmic goiter and cardiac neurosis, the oxygen consumption, the minute volume of the heart, ventilation, blood pressure and the pulse rate were investigated during rest and after work on the stairs. The author's conclusions were that: 1. The increase in oxygen consumption as a percentage of the resting value after a fixed amount of work on the stairs varies within fairly narrow limits in healthy individuals and is independent of body weight, provided the latter is within physiologic limits. 2. In cases of decompensated heart disease and cases of decompensated hypertonia, this increase is consistently greater than in the healthy subjects, so that it seems to be a reliable measure of pronounced heart insufficiency, though it is of more doubtful value with borderline cases. At the same time as the insufficiency yields to treatment, a reduction of the oxygen consumption after work often sets in. 3. The increase in ventilation after work is a far less reliable measure of the decompensation than the increase in oxygen consumption. 4. The pulse rate, utilization and standard metabolism are increased in many cases of decompensated heart disease and hypertonia during rest, but, on the other hand, the minute volume, the minute volume per square meter of body surface and the systolic output, are reduced. Determinations of these functions of the circulation cannot be used, however, as a method of functional heart diagnosis, as the values for healthy subjects and cases of decompensation partly overlap. 5. The systolic output per square meter of body surface in the decompensated cases appears to be considerably reduced, so that its determination is of greater importance than that of the functions mentioned in the fourth conclusion. 6. The utilization, i. e., the oxygen absorption, per liter of blood, after a fixed amount of work returns more quickly to the resting value in healthy persons than in cases of severe decompensation. 7. The return of the systolic blood pressure and pulse rate to the resting value, after a fixed amount of work, is slower in cases of decompensation than in healthy persons. Owing to the fact that the distribution of the values for healthy persons and cases of decompensation partly overlap, determinations of these functions severally cannot be used as measures of heart insufficiency. 8. The return of the Liljestrand-Zander product is retarded in cases of decompensation.

It seems somewhat doubtful in view both of the paucity of the material and of the results whether this functional test following Nylin's method is of practical value in determining the presence or absence of cardiac insufficiency. By the time any of the tests that have been noted in this volume show clear-cut deviations from the normal there are other simple clinical evidences of cardiac insufficiency. In the borderline cases these tests are not of great value.

Diagnosis and Treatment of Diseases of the Liver and Biliary Tract. By Various Contributors. Methods Employed in the Combined Medical and Surgical Clinic for Diseases of the Biliary Tract. New York Post Graduate Medical School, Columbia University. Paper. Pp. 41, with illustrations. New York, 1934.

This booklet enumerates in outline form the recognized procedures required for examinations in the medical and surgical clinic for diseases of the biliary tract. An outline of the plan of investigation indicates that complete histories and physical examinations are made and that roentgenologic studies of the gallbladder and if indicated of the gastro-intestinal tract, studies of the urine, blood and gastric contents, the bacteriology

cytology and crystallography of the bile obtained by drainage, and chemical studies of the blood for cholesterol, urea and sugar are carried out. The charts are comprehensive. Several pages are devoted to the technique of biliary drainage, with special stress laid on the manner of searching for typhoid carriers by the bacteriologic study of the bile. On the page enumerating the microscopic observations, no mention is made of animal parasites. This is probably an oversight. The techniques of the methods of chemical study are given in detail and the results discussed briefly. The authors use various diets adapted to a varying symptomatology, such as presence or absence of infection, the state of nutrition, association of liver disease, gastric or intestinal irritability, jaundice, fat indigestion, patency of the cystic duct, tonicity of the gallbladder, presence of calculi, and cholesteremia. Much might be disputed but as this is an outline of the procedure used by the authors and not offered as a definite contribution at this time, it would be out of place to enter into a discussion at present. The last two sections are devoted in more or less skeleton form to the indications for surgical treatment and the management of disease of the biliary tract in pregnancy. This outline is interesting and complete and would seem to be a usable framework for an excellent book on biliary tract disease.

The Effects of the Economic Depression on Education in Other Countries. By James F. Abel. Chief, Division of Foreign School Systems, Office of Education. Bulletin 193, No. 14. United States Department of the Interior, Office of Education. Paper. Price 5 cents. Pp. 37. Washington, D. C. Supt. of Doc. Government Printing Office, 1933.

This is a statistical survey of the effects of the economic crisis on education during the years 1929-1932. On such subjects as school budgets, capital outlays, teachers' salaries, unemployment attendance and school consolidation data have been accumulated from official reports. Condensed summaries have been prepared for a number of individual countries. Such a compilation may prove a useful guide for students of educational administration.

Workmen's Compensation Acts. Duty of Employer to Supply Continuing Medical Care in Case of Permanent Disability.—In the course of his employment, in 1929 Nee fractured his spine. Paralysis from the hips downward followed. Since the accident he has been confined in a hospital, hopelessly bedridden and utterly unable to help himself. He requires special food and services that can be furnished only in a hospital. According to the evidence, no medical surgical or hospital care can reduce his disability or restore him to a gainful occupation. In 1931, the industrial commission awarded him compensation and directed his employer to pay hospital and medical bills amounting at that time to more than \$10,000 and to furnish such medical and hospital services in the future as Nee might require. On appeal the award was affirmed by the superior court Cook county and the employer appealed to the Supreme Court of Illinois.

Nee's employer raised no question as to its liability to pay compensation for permanent total disability but it asked for an adjustment of the claim for continued payment for medical and hospital services. The workmen's compensation act provides:

"The employer shall provide the necessary first aid medical and surgical services and all necessary medical, surgical and hospital services thereafter limited however to that which is reasonably required to cure or relieve from the effects of the injury." *Smith-Hurd's Illinois Revised Statutes 1931 c. 48 sec. 145 (a)*

Nee's employer contended that this does not require an employer to furnish medical and hospital services indefinitely but to furnish them only to such an extent as may be reasonably necessary to cure or relieve the injured employee from the effects of the injury. Cure and relieve the employer argued have essentially the same meaning and when it has been determined that disability cannot be cured, reduced or relieved then the employer cannot be required to continue to provide medical and hospital services. The burden of such

further care should fall on society through its publicly or privately endowed institutions.

The Supreme Court, however, was unable to construe the words "cure" and "relieve" as meaning the same thing. A workman who is cured is relieved from the effects of his injury, but one who cannot be cured may still need attention to relieve him of pain or other injurious effects by his injury. These are the only natural and usual meanings of these words. The workmen's compensation act is a humane law of a remedial nature, and wherever construction is permissible the act should be liberally construed. It would be nothing short of judicial legislation, in an exceptional case, to impose on the act the limitation contended for by Nee's employer. A reasonable interpretation of the act requires that the employer's liability continue as long as medical and hospital services are needed to relieve the injured employee from the effects of his injury. The award of the commission was accordingly affirmed.—*Accman Co v Industrial Commission (Ill.) 187 N. E. 137*

Workmen's Compensation Acts. Loss of Function of Testicles Compensable.—In the course of his employment, Gleason's clothing caught on a revolving shaft and everything except his shoes and a sleeve of his jacket was torn off. Half the body of his penis and the entire scrotum were pulled off and his testicles left hanging by elongated spermatic cords. He was taken to a hospital where a physician placed the right testicle in the anterior wall of the abdomen. The left testicle he placed above what remained of the penis, in an artificial sac of grafted skin taken from the inner surface of Gleason's thighs. There was no infection and Gleason left the hospital about seven weeks after the accident. He claimed compensation under the workmen's compensation act and sought to have the award based in part on the rating fixed by the act for the loss of both testicles. He was 29 years old but after the accident experienced no sexual sensations, had no normal desire for sexual intercourse and had no erection. His physician testified that because of the skin grafting he would never be able to have an erection or to have sexual intercourse, and he believed that the testicles would never be "usable." The industrial commission made an award in Gleason's favor, but on appeal the circuit court, Lee County, set aside the award for the loss of the testicles. Gleason thereupon appealed to the Supreme Court of Illinois.

The workmen's compensation act authorizes compensation for the loss of both testicles "50 percentum of the average weekly wage during one hundred fifty weeks." *Smith-Hurd Rev. St. 1933 c. 48 sec. 145, par. (c) subd. 163½*. Gleason's employer contended that this language was not sufficient to authorize compensation for the loss of use of testicles, but only for their loss. On behalf of the employer it was argued that since the testicles had been successfully grafted into Gleason's body, there had been no "loss" within the meaning of the act. This argument, said the Supreme Court, is without legal weight in Illinois. Incapacity to use need not be tantamount to an actual severance. The loss of a member is complete when its normal use has been taken away. In this case the testicles were not only lost from their usual and natural resting place and sewed up in separate compartments elsewhere but they were lost in the more serious sense that they never again could perform their normal function having to do with sexual intercourse and the propagation of offspring. Under any reasonable view an injury to an employee under the workmen's compensation act which renders his testicles useless for the performance of their normal function is compensable. The Supreme Court accordingly affirmed the award of the commission.—*Northwestern Barb Wire Co v Industrial Commission (Ill.) 187 N. E. 468*

Hospitals. Criteria of Charitable Character.—The city of Palo Alto owned the Palo Alto Hospital. It gave possession of the hospital and its equipment to the Leland Stanford Junior University which agreed to make an annual statement of the receipts and expenditures of the hospital and after deducting operating expenses and any working fund that might be agreed on to pay the balance to the city. The university from the tuition fees of each student paid a stated amount to a students' guild to pay the operating expenses of the hospital. A student

entering the hospital paid only a part of the expense of treatment, the balance being paid out of the funds of the guild. The hospital gave no free service to any one. There were no free beds for which the hospital itself bore the expense. When the hospital received a patient who was not able to pay, payment was made by a charitable organization, known as the Palo Alto Hospital Auxiliary.

Mrs. Baker, a patient in the hospital, undertook to turn on an electric lamp. When she touched it, she received an electric shock so severe that she could not release her hand until after a nurse had disconnected the lamp from the electric current. It was later discovered that a part of the insulation surrounding the key which served to turn the light off and on was broken. The accident caused a third degree burn of Mrs. Baker's right hand, necessitating the amputation of her little finger and the removal of some of the little bones of her hand. The shock caused, too, great pain and seriously affected her nervous system. She and her husband sued the hospital and were awarded \$10,000 and \$1,000, respectively, as damages. From the judgment the hospital appealed to the district court of appeal, first district, division 1.

The hospital contended, among other things, that it was a charitable institution and had exercised due care in the selection of its employees. The district court of appeal, however, was of a different opinion. The hospital was not formed and maintained for charitable purposes. No charity was dispensed by it. On the contrary, it charged rates usually and customarily charged by other hospitals. It made no pretense of receiving patients unable to pay for the service rendered except when payment was guaranteed by the Palo Alto Hospital Auxiliary, an independent organization. Moreover, in California a corporation organized for public charity might conduct also an enterprise for gain and be liable for the negligence of its employees in that enterprise, even though the profits derived from it were devoted to the general purposes of charity (*Stewart v. California Medical etc., Ass'n*, 178 Calif 418, 176 P 46). The court did not regard the damages awarded as excessive.

The judgments of the court below were affirmed—*Baker v. Board of Trustees of Leland Stanford Junior University* (Calif.) 23 P (2d) 1071.

Medical Practice Acts. Revocation of License Not Barred by Statute of Limitations.—The California board of medical examiners revoked Bold's license to practice medicine. In a review of the board's action by the district court of appeal second district, division 2, Bold contended that the proceedings against him were barred by the statute of limitations. The provisions of the California code of civil procedure relating to the commencement of civil actions, said the court, relate only to actions or civil proceedings in courts, not to hearings before boards. The board of medical examiners is not a "court," even though it exercises power of a judicial nature. The purpose of the medical practice act is to exclude undesirable persons from the medical profession. The staleness of a charge against a person does not necessarily make it reflect less on his character. The determination of the effect of staleness belongs exclusively to the board of medical examiners. No statutory bar is applicable.

Two charges against Bold were pending at the time of the hearing before the board. The board heard evidence tending to show that his license should be revoked. It decided that his license should be revoked on the basis of the evidence offered in support of one of the pending charges, in which it was alleged that he had performed a criminal abortion. It then voted to revoke his license on the basis of a second charge, alleging that he had performed an abortion in another case. The latter case formed the basis of the appeal here under consideration. Bold contended that the revocation in this case was not authorized, because when the board revoked his license on the basis of the first charge it lost jurisdiction and authority over him. The appellate court, however, could see no merit in Bold's contention. The board had jurisdiction over both charges. Its decisions could not be made simultaneously, however, but had to be made successively. The judgment of the superior court, Los Angeles county, affirming the action of the board of medical examiners was affirmed by the appellate court—*Bold v. Board of Medical Examiners* (Calif.), 23 P (2d) 826.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

Treatment of Convulsive and Nonconvulsive Toxemia

—Thomas institutes treatment immediately if, in spite of the hygienic rules laid down for the patient the symptoms of nonconvulsive toxemia develop if the blood pressure begins to rise and if there is a sudden increase in body weight due to water retention and a diminished urinary output with frequency albuminuria, slightly accelerated pulse, headaches, numbness and tingling of the fingers, lassitude and malaise. The patient is put to bed and must have absolute rest. Mental rest is imperative and is best secured by the proper application of sedatives. Sodium amytal may be given in doses of 3 grains (0.2 Gm), and may be repeated as often as necessary to produce rest. In order to relieve water retention in the tissues and to lessen the load on the kidneys intestinal excretion is to be encouraged. A salt-free, nonprotein diet is indicated until the symptoms subside. A diet rich in carbohydrates is essential; this is readily available in the form of fruit juices, cereals, custards, milk and vegetables, with dextrose added as required. The blood pressure curve, intake and output, pulse, body weight and any unusual subjective or objective symptoms that may develop should receive untiring attention. A twenty-four hour specimen of urine should be measured and examined. With improving conditions, the patient may gradually return to the normal diet containing not too much meat or fluids and little salt. From one to two days each week should be set aside as vegetable days. The patient who has once shown the slightest evidence of toxemia, regardless of how well she responds to treatment should be seen at frequent intervals and kept under close observation. If the course of the disease is slow but progressive with gradually increasing symptoms, chronic nephritis or low kidney reserve is suggested and treatment is to be intensified if possible.

Metastatic Tumors of the Heart—In a study of 327 necropsies on patients with known malignant manifestations, Burke found fourteen cases of metastatic involvement of the cardiac muscle. This constitutes approximately 4.3 per cent of routine necropsies made in such cases at the state institute for the study of malignant disease. While this proportion seems somewhat higher than a review of the literature would indicate, it can probably be explained by the fact that this series includes only cases in which malignant disease was definitely the cause of death.

Internal Secretions and Metabolism of Malignant Tumors—According to Meyer and McTiernan, the effect on the metabolism of transplanted mouse tumors of the bodily administration of various hormones is insignificant save for thyroxine and insulin. In a distinct majority of experiments thyroxine appreciably inhibits the oxygen consumption of the tumor, both sarcoma 180 and carcinoma 63 simultaneously, thyroxine strikingly stimulates the metabolism of isolated liver tissue. The aerobic and anaerobic glycolysis of sarcoma 180 is not increased after bodily administration of thyroxine. Microscopically, the sarcomas of thyrotoxic mice resemble the tumors of the normal mice. The administration of insulin brings about a decrease in the anaerobic glycolysis of mouse sarcoma 180. Several of the other hormones seem to have a depressing effect on liver metabolism, and that of theelin is most striking. The effects on tumor and liver following the removal of various glands of internal secretion are inconsistent. Only thyroidectomy appears to bring about a depression of the metabolism of both, and this is not striking and is hardly constant enough to appear significant. Further experiments after thyroidectomy are necessary. Thyroxine seems to inhibit tumor growth, but no other hormone has any demonstrable effect on the tumor development nor does removal of the glands of internal secretion prevent the usual rapid growth of the sarcoma.

Quinidine Sulphate Electrocardiograms—Maher and his associates administered quinidine sulphate to nineteen patients; ten received 30 grains (2 Gm) and three 60 grains

(4 Gm) orally per day and six received intravenous injections of from 3 to 5 grains (0.2 to 0.3 Gm) without general toxic effects. The electrocardiograms of the majority of these patients showed changes only in regard to the T waves within from twenty-four to seventy-two hours if orally administered, and immediately if given intravenously. These changes varied from mild flattening to sharp inversion of the T waves. The duration of the effect varied from three to six days on oral administration and three hours on intravenous administration. Changes in the QRS and PR intervals are presumably effects produced by intoxicating doses. On the basis of their studies with doses of from 30 to 60 grains, administered orally over a period of from five to nineteen days, or intravenous injections of from 3 to 5 grains, it would not appear that the reported observations of changes in the P wave, PR interval or QRS complex were verified. The conclusions of T wave changes were sustained simply. In discussing these discrepancies it is the authors' opinion that changes in the contour of the P waves may normally occur in any series of electrocardiograms taken over a period of time. In another series of experiments of the effects of quinidine sulphate on the fibrillating auricle the reports of which have not as yet been published, they have found that when intoxication of the cardiac muscle appears with heavy doses such as intravenous injections of 5 grains every four hours for four doses or from 10 to 12 grains (0.65 to 0.78 Gm) in one injection in some cases there was lengthening of the QRS complex as well as marked notching and slurring and appearance of frequent extrasystoles as well as ventricular tachycardia.

Hematopoietic Substance in Gastric Juice.—To determine whether it was possible to separate the 'active principle' in the gastric juice from the known enzymes (pepsin and rennin), Fouts and his associates subjected human gastric juice to ultrafiltration. It was found impossible to separate the enzymes, pepsin and rennin, from the hematopoietic substance in human gastric juice except after concentration of the gastric juice by vacuum distillation. The process of concentration by vacuum distillation or storage in the icebox for two months was necessary before the presence of a substance capable of producing a reticulocyte response when injected into patients having pernicious anemia could be demonstrated. The authors discuss the possible mechanisms involved in this change in the gastric juice.

Pentnucleotide and the Treatment of Agranulocytosis.—The Reichs' experimental data reveal that in the case of the rat injections of pentnucleotide have little effect in stimulating or improving the maturation of the blood cells. The total white count, Schilling and lymphocytic indexes, reticulocyte percentage and bone marrow differential react about the same after injections of physiologic solution of sodium chloride as after pentnucleotide. Regeneration after benzene poisoning occurs just as quickly with injections of physiologic solution of sodium chloride as with pentnucleotide. The authors argue that, if x-rays act through the pentnucleotide mechanism, it seems logical that injections of pentnucleotide would improve the maturation of red cells as well as of polymorphonuclear neutrophils. This has not been the case in their work. The doses of pentnucleotide were large in proportion to the weight of the rats and should have been sufficient to cause the changes expected. The hematopoietic system of the rat is different from that of man but if the bone marrow of the rat was depressed by benzene just as in the case of man it ought to be stimulated by the same agents that are supposed to stimulate the human bone marrow. The authors further recognize that other possible variants prevent the deductions of the experiment from being applied unqualifiedly to the treatment of human agranulocytosis. Their observations emphasize the vital importance of adequate controls may help to throw light on some of the disappointing results obtained in the treatment of agranulocytosis with pentnucleotide, and may also lend support to those who believe that many patients having agranulocytosis recover by themselves and that a large percentage of the beneficial results attributed to the various forms of therapy for this condition may be just coincidental. The practically negative experimental results cast some doubt on the value of pentnucleotide in the treatment of agranulocytosis.

Secondary Carcinoma of Tubes.—Sampson studied fifteen cases of carcinoma of the tubes and ovaries. By continuous extension, carcinoma of the body of the uterus invades pelvic structures. Secondary carcinoma of the tubes and ovaries arises from the continuous permeation of the lymphatic canals and also from earlier emboli. By the continuous extension of carcinoma of the body of the uterus the mucosa is replaced by the growth, and when situated in a uterine horn it frequently extends through the uterine opening of the tube and replaces the mucosa of the uterine portion of the tube. Portions of cancer are broken off from the growing (advancing) portion of the growth in this situation and as emboli migrate into the tube beyond. Superficial carcinomas are found in the mucosa of the tubes, in their fimbriae and on the ovary and peritoneum of patients having carcinoma of the body of the uterus. They present the same histologic structure as recognized implantation carcinoma of the lining of lymph vessels and also on the peritoneum from ovarian carcinoma with evidence that particles of cancer from the primary uterine growth could have reached the site of these metastases through the lumens of the tubes. The author believes that their pathogenesis in many instances is the same, namely, the lodging of the cancer cells on the surface of their host, injury to that surface already present or created by the carcinoma, and the attempted repair of the injury with the continued growth of the carcinoma in this situation. In like manner, particles of uterine carcinoma become implanted in the uterine and cervical mucosa and in wounds of the vagina and of abdominal incisions.

The Heart in Experimental Scurvy with Superimposed Infection.—Rinehart and Mettier studied the effect of scurvy and scurvy combined with infection (beta streptococcus) on the valves of the heart and muscle in the guinea pig. Infection in animals maintained on an adequate diet usually produces no significant lesions in the valves of the heart. When they occur they are of an exudative rather than proliferative type. In uncomplicated scurvy, definite atrophic and degenerative changes occur in the collagenous stroma of the valves of the heart.

In scurvy with added infection, striking lesions of a combined degenerative and proliferative character develop in the valves with considerable frequency. The experimental endocarditis so produced was similar to that of acute rheumatic fever. Degenerative and proliferative lesions occur in the cardiac muscle and pericardium of the experimental animals subjected to combined scurvy and infection, which are considered similar in type to the Aschoff reaction. Organisms other than the beta streptococcus may, in the presence of scurvy, produce such lesions. Lesions resembling the "fibrinoid degeneration" of Klinge have been seen in various sites in animals subjected to combined scurvy and infection. Klinge considers this type of degeneration the characteristic and initial lesion of rheumatic fever. Evidence indicates that there is some factor other than simple infection that contributes to the development of rheumatic fever. Experimentally, infection alone or scurvy alone will not produce significant lesions but when scurvy and infection are combined striking lesions are produced, particularly in the valves of the heart. The authors advance the theory that a condition of vitamin C undernutrition may be a necessary background for the development of rheumatic fever when the result of infection is combined with the scorbutic state, the pathologic picture of rheumatic fever develops.

Influence of Emotion in Precipitating Convulsions —

To determine how frequently emotion acts as a precipitating factor in convulsions, Fremont-Smith has studied forty-two unselected private patients. All suffered from generalized convulsions with loss of consciousness. In thirty-one a direct relationship has been found between emotion and one or more of the major convulsions. In several instances all or nearly all the attacks have been immediately preceded by strong emotion, usually fear, guilt or frustration. That such emotion has causal relation to the convulsions is indicated by the fact that in eight cases major or minor attacks have been precipitated under observation by a discussion of the emotional difficulty. In three cases attacks apparently could be precipitated by the physician at will by such discussion. Psychotherapy has been of definite value in several of these cases not only by helping the patients to a better adjustment of their major conflicts but more specifically by bringing back to consciousness the suppressed emotion so that they may see clearly the relationship of the emotion to the attack. The theory that stimulation of the sympathetic nervous system by emotion plays an important part is supported by the fact that convulsions are occasionally precipitated by pain and by cold. Emotion, pain and cold are well known stimulators of the sympathetic nervous system. Moreover the onset of acute infections frequently precipitates convulsions in predisposed persons. Here again the sympathetic nervous system is strongly stimulated. Whether the stimulation of the sympathetic nervous system precipitates the convulsion by cerebral vasoconstriction or by some other mechanism is not known.

Red Back Spider Bite and Magnesium Sulphate Treatment —DeAsis points out that the clinical manifestations resulting from the bite of *Latrodectus hasseltii*, or the red back spider, are elevated blood pressure, slow, often weak, pulse, rapid often labored respiration, profuse perspiration, general weakness and numbness, muscle pains and paralysis of the lower limbs. The poison may prove fatal. It seems to have a special predilection for the peripheral nerves and nerve endings. The central nervous system seems to be only slightly affected if at all. The poison travels by way of the lymph canals and is vasoconstrictor in action. A 25 per cent solution of magnesium sulphate if administered intravenously, is efficacious for the bite of the red back spider. Magnesium sulphate, administered intravenously, is worthy of trial for the bite of *Latrodectus mactans* (black widow) since the symptoms produced by this spider and those produced by the red back spider are in many respects similar if not identical. The black widow spider is common in parts of the United States, South America and Hawaii.

Paroxysmal Ventricular Tachycardia—Lundy and McLellan agree that the basic mechanism underlying this arrhythmia (paroxysmal ventricular tachycardia) is laid down by disease of the ventricular musculature. Evidence is advanced which tends to show a relationship of different kinds of heart disease to different types of this arrhythmia. The mechanism involved in determining the type of this arrhythmia is considered to be heart disease which involves one ventricle more than the other, or a region of one ventricle more than the remainder of the same ventricle and thereby influences the type according to the ventricle, or its part which has the greater involvement. The two types (right and left) may arise from the same ventricle (the left) in different locations. Changed cardiodynamic balance between the two ventricles may be a factor in determining the type by exerting more wear on one ventricle. The basic causes of this arrhythmia are listed and are related to the types as follows: 1 Arteriosclerotic, hypertensive and syphilitic heart diseases are associated in the highest percentage of instances with the left ventricular type. 2 In coronary thrombosis the type is influenced by the location of the infarct. 3 Pulmonary disease, especially pneumonia, was of higher incidence in the right ventricular type. 4 The effect of valvular disease could not be determined. 5 Age exerted an influence. 6 The stage of heart disease was associated in a definite manner. 7 Men develop this arrhythmia twice as often as women. 8 Undetermined heart disease was found in 32 per cent of the reported cases and had a greater relationship to the right ventricular type. 9 No demonstrable heart disease was present in 14 per cent of the cases, most commonly in the right ventricular type. The exciting causes of this arrhythmia are listed and are related to excess digitalis administration, coronary thrombosis, exertion, decompensation, auricular fibrillation, flutter, and nervous and emotional factors. Paroxysmal ventricular tachycardia is seen most frequently in the fourth and fifth decades. The prognosis is utterly grave in the alternating bidirectional type and only relatively less so in the left ventricular, idioventricular and right ventricular in the order named. In the absence of demonstrable heart disease the prognosis is best in the right ventricular type. Death occurred during the period of observation in 47 per cent of the ninety-six patients whose histories were studied.

Radiation Treatment of Hyperthyroidism—Pfahler believes that radiation is indicated in all cases of hyperthyroidism in which the patient is not in crisis or is not suffering from definite pressure symptoms. He recommends operation in all simple or nontoxic goiters unless there is some contraindication, in which case a moderate amount of radiation may be used. At times good results are obtained even with large goiters of this type. After using radiation therapy in 533 cases of goiter the author states that irradiation with either x-rays or radium may be accepted as a useful method of treatment of hyperthyroidism, since the end-results are approximately equal to those obtained by surgery. The fear of operation or delays preceding operation are likely to lead to cardiac impairment. This delay can be eliminated by the use of radiation therapy, which does not involve pain, shock or great inconvenience. Associated medical care and general directions for the conservation of energy are essential. The author employs

x-rays, using 130 kilovolts, 5 milliamperes, at from 25 to 30 cm distance with the equivalent of 6 mm of aluminum filter. The cervical region is divided into four fields, approximately 5 by 15 cm in size. Two of these are anterior and two are posterolateral. The lower border extends down over the thyroid region. The larynx is protected with lead. The rays are directed medially and downward, so that a crossfiring effect is obtained in the region of the thyroid. The four areas constitute one series and they are usually given in one day, this series being repeated in three weeks and then in four weeks the interval being increased according to the improvement obtained. In simple or colloid goiters, from 30 or 40 per cent skin erythema doses may be given through the four fields without danger of producing hypothyroidism. These several small doses will often be sufficient to show a definite decrease in size. In adenomas, localized doses are usually employed the adenoma being cross-fired through two portals. In the mildly toxic cases in which 50 per cent skin erythema dose may be given through each of four portals. This is repeated in three weeks and then the amount is decreased and the interval is increased. In the severer cases it is better to begin with smaller doses not exceeding 40 per cent of the skin erythema dose at the first series. This may be increased at subsequent series. More than six series are rarely necessary. The author employs roentgen radiation as a routine procedure. Of his 533 patients 87.9 per cent were either cured or markedly improved.

- *Dissociation of Homologous Muscle Function in Stuttering L E Travis, Iowa City—p 127

Viscosity of Muscles in Catatonic and Parkinsonian Rigidity—Finkelman states that the muscles of patients suffering from catatonic dementia praecox possess a high degree of elasticity and but little internal friction (viscosity). Catatonic rigidity differs in this respect from the rigidity of chronic encephalitis. Pollock and Davis cite the fact that the muscles of patients suffering from parkinsonism possess both high internal resistance of so called viscosity and a large viscous elastic flow. The difference between the muscle tonus curves of chronic encephalitis and catatonia is evidence that the muscle rigidity in these two conditions is not due to physiologic interruption at the same levels.

Method of Investigation of Cerebellum and Red Nucleus—Mussen presents a method with which it is possible to see the reactions that are produced in a normal animal, the success of which depends on the correct insertion and fixation of a bipolar electrode into the region to be examined. The electrode is composed of two iridioplatinum wires fastened to terminals in a vulcanite base and insulated in glass tubes. The base fits into a metal cup, which is screwed into the bone. The cup directs the electrode while it is being inserted, and by means of a bayonet joint attachment holds it firmly. A cylinder with a flange screws over this to keep the tissues from the electrode, and about this the skin and muscles can be closed firmly. Finally a cap is screwed over the cup to protect the terminals. The size of the electrode is 1.5 mm. in diameter the length varying according to the depth from the surface of the bone of the structure to be investigated. The trephine is 5 mm. in diameter. The brain is not exposed, only the dura being punctured. The animal is anesthetized and the head fixed in the stereotaxic instrument. Measurements of the head are taken, the indicator is adjusted and the position of the structure to be examined is marked. The skull is then trephined and the cup of the electrode unit is screwed into the bone. The bipolar electrode is next inserted, the flange is screwed on and then the cap. The skin and muscle are closed

tightly about the unit, and the field of operation is bandaged. On the following day, when the animal has completely recovered from the effects of the operation, the bandages are removed, the animal is entirely unrestrained and the success of the examination depends on its cooperation. By gentle treatment the ordinary cat will respond normally by purring. The presence of the electrodes in the skull does not cause any pain or uneasiness. With the animal in a friendly mood it is put through a number of simple tests. The gait and righting reflexes are observed, and also its ability to jump from a table and walk backward on the hind legs when it is supported by the shoulders. The cat frequently purrs contentedly. The next event consists of attaching the plug from the faradic battery and testing the reactions. The author's report deals with the results obtained from the red nucleus, the anterior region of the thalamus and the cerebellum. The strength of the current is indicated by the sensation produced by the points of the electrode when applied to the tip of the tongue. With the secondary coil at 17 cm a slight tingling is felt at 13 cm, the sensation is painful, contraction begins at 12 cm and is marked at 8 cm.

Stuttering—Travis recorded action currents simultaneously from the two masseter muscles during stuttering and during free speech of both the stutterer and the normal speaker. Twenty-four adult stutterers and an equal number of normal speakers served as subjects. In general, during normal speech the action currents from the two masseter muscles were identical, while during stuttering those from one masseter muscle were strikingly different from those of the other. These observations indicated a unified control by the central nervous system of the two sides of the speech mechanism during normal speech and a lack of such control during stuttering.

Intranasal Operation on Ethmoid Sinus—Monson describes a new method for the surgical care of the diseased ethmoid sinus. The patient is given a preliminary dose of sodium ethyl barbiturate (from 3 to 4½ grains [0.2 to 0.25 Gm.]) thirty minutes before being sent to the operating room. The mucous membranes are shrunk with tightly wound cotton on the end of wire applicators which have been dipped into a solution of equal parts of 20 per cent cocaine and 1,000 epinephrine hydrochloride. In most cases, a preliminary submucous resection is advisable to obtain more room and provide a better view for the ethmoid dissection. If polyps are present, they must be removed at this time. Then a linear incision is made along the anterior half of the lower border of the middle turbinate and a submucous resection of this structure is performed with a Freer septal elevator. This mucous membrane and the superior turbinate are carefully preserved. The remainder of the middle turbinate is then amputated throughout its length with a pair of curved nasal scissors. The Bulla cells are next broken into by an ethmoid forceps and the dissection is carried backward by successive bites until the anterior wall of the sphenoid sinus is reached. The remainder of the dissection of the ethmoid sinus is then continued by working carefully upward until the solid bone separating the nose from the anterior fossa is reached and cleared of bony partitions and sinus mucous membrane. Likewise, all the partitions are broken down laterally until the lamina papyracea is reached and cleared throughout its length. The agger cells are removed by means of a Pratt ethmoid curet. Halle's method of turning down the flap of mucous membrane in the agger region and chiseling away the cells should be used when there is considerable hypertrophy of the agger cells and the uncinate process. Loose spicules of bone and debris are carefully removed by the use of nasal

forceps. A nasal forceps is placed between the septum and the superior turbinate, and the latter is fractured laterally. Iodoform gauze or gauze containing compound tincture of benzoin is placed loosely in the space between the septum and the medial wall of the ethmoid capsule, in order to hold the latter in place. This is removed in twenty-four hours. The postoperative care consists in the use of mild antiseptic mentholated oily drops after the removal of the gauze. Care must be taken that synechiae are not allowed to form between the septum and the mucous membrane of the medial wall of the ethmoid capsule. These structures soon become adherent to the upper and lateral walls of the nose, providing most of that region with a normal mucous membrane covering.

Effects of Drugs on Ciliary Activity of Upper Respiratory Tract—Lierle and Moore determined the effects of certain drugs on the ciliary activity of strips of tissue mounted in a special microscope chamber and the effects of a larger number of drugs on the ciliary activity of the unbroken mucosa of the turbinates of freshly killed guinea-pigs. They observed that tap and distilled water when applied to the mucosa of the upper respiratory tract cause slowing of the ciliary beat. A 3 per cent solution of ephedrine hydrochloride is not detrimental to ciliary activity but at times increases it slightly. A 5 per cent solution of cocaine hydrochloride is not detrimental to ciliary activity, but 10 and 20 per cent solutions produce definite slowing, with good recovery. Mild silver protein in concentrations of 5, 10 and 20 per cent produces an initial speeding of ciliary activity. This is followed by a slowing, which may be due to the water solvent rather than to the drug. A 0.5 per cent solution of eucalyptol has no deleterious effect on ciliary activity. A 0.5 per cent menthol and, to a greater degree, 1 per cent menthol have a mildly depressing effect on ciliary activity. Thymol in 1 and 0.5 per cent concentrations and 1 per cent eucalyptol, in the order named, are definitely detrimental to ciliary activity. A 1,000 solution of epinephrine hydrochloride, 2 per cent zinc sulphate and 2 per cent mercurchrome in the order named, are definitely detrimental to ciliary activity. Silver nitrate in a 0.5 per cent concentration is immediately and fatally detrimental to ciliary activity. In no instance was it possible to start the cilia beating again after its application.

Teratoma of the Testicle—After a study of fifteen cases of malignant tumor of the testicle and a review of the literature Stelle is of the opinion that practically all malignant testicular growths are either embryonal carcinomas or embryonal adenocarcinomas of teratomatous origin. No other type of malignant disease of the testicle has been seen at the United States Naval Hospital since June 1930. That another type does occur has been pointed out by Stevens and Ewing and by Bell who described an adult teratoma. In the cases in which either the original tumor or active metastases were present prolan A could be detected in the urine biologically, by means

of the method of Aschheim and Zondek. The author gives the diagnosis, differential diagnosis and treatment of teratoma of the testicle and emphasizes the importance of making a quantitative test for prolan A in all cases that show a negative qualitative reaction. Only fifteen cases of teratoma of the testicle occurred in 14,381 general admissions to the hospital in a period of twenty-eight months. During the same period there were approximately 620 cases of cancer, in 0.024 per cent of which the growth was a teratoma. Teratoma of the testicle is relatively radiosensitive, and treatment by external radiation and by surgical intervention produces results varying from complete cures to palliative effects, assuring the patient months or years of life comparatively free from disease.

Tumors of Sympathetic Nervous System—The three types of tumors (neuroblastoma, paraganglioma and ganglioneuroma) that Lewis and Geschlechter discuss develop from cells that wander out from the neural crest during embryonic life. The undifferentiated cell may give rise to the neuroblastoma, and as differentiation proceeds the more adult types of paraganglioma and ganglioneuroma may develop. The occurrence of all these types of tissue in the same tumor indicates a common origin; different degrees of differentiation accounting for the occurrence of the more adult type of tissue. Recently Joergensen has reported a case of hypertension associated with a retroperitoneal ganglioneuroma. Softening in the brain and spinal cord was also noted. In discussing this case he stated that paraganglioma has been found associated with hypertension without other discoverable etiologic factors. Some paragangliomas are composed of epinephrine-bearing tissue while ganglioneuromas do not contain such elements. One may conclude therefore that 'in spite of the origin of these two tumors from the common primitive type of cell when hypertension is associated with ganglioneuroma it is merely incidental. It is believed that the hypertension in this case can best be explained on the basis of the renal and generalized vascular changes. No other ganglioneuromas have been reported in which hypertension was a part of the clinical picture.

Ewing's Tumor (Primary Intracortical and Subperiosteal Lymphangio-Endothelioma)—De Santo reports a case of primary intracortical and subperiosteal lymphangio-endothelioma so designated because the tumor could be traced to the perivascular lymphatics of the haversian canals and to those beneath the periosteum, and because the tumor cells secreted lymph. The clinical course and the gross and microscopic pathologic picture of this tumor satisfied every criterion of so-called Ewing's tumor. The conception that Ewing's tumor is a primary osteolytic tumor of the medullary cavity is erroneous. Probably in every true case Ewing's tumor is a lymphangio-endothelioma, originating in the lymphatic endothelium of the haversian canals and in that beneath the periosteum. Involvement of the medullary cavity while prominent, is probably secondary. This concept is in harmony with anatomic knowledge of the lymphatics of the bones, for lymphatics have never been demonstrated in the bone marrow, whereas perivascular lymphatics in the cortex and beneath the periosteum are well known. Even should the existence of lymphatic spaces in the bone marrow be demonstrated at a future date the validity of the concept would not be destroyed, since medullary involvement might readily occur by transformation of normal lymph endothelium into a neoplasm.

Treatment of Infected Brain Wounds with Bacterial Filtrates—Branch and his associates give the results they obtained in treating with bacterial filtrates eight patients with open infected wounds of the head involving the brain. Two patients with severely infected wounds on the surface of the brain showed marked improvement within four days following frequent applications of a polyvalent streptococcus staphylococcus filtrate to the dressings. Prior to treatment with the filtrate they had shown no improvement with irrigation and dressings with surgical solution of chlorinated soda. The authors stress the points that appear to be requisite for success with this type of treatment: 1. Exposure must be complete, so that the whole infected surface is brought in contact with the dressings. 2. The dressings should be moistened with the filtrate at frequent intervals. 3. The infection must be focal and limited to the surface of the wound. Theoretically this therapy should work with rapidity when the proper filtrate is

brought in good contact with bacterial growth in sufficient concentration to cause lysis of the organisms. Practically, the results seem to become apparent within about four days or less in cases with surface infection of thoroughly exposed wounds when the dressings are repeatedly moistened with the proper filtrate. Failure to obtain improvement within four days may be taken as an indication of improper contact or of insufficient concentration that is, of a poorly matched filtrate, inadequate exposure of the wound, a deep or disseminated infection or some other clinical complication.

Perineal Repair Following Labor—Fist devised a simple technique that brings perineal muscle and fascia together in front of the rectum by means of interrupted buried, submucous, mattress eight sutures. Incision of the mucosa is not necessary. This procedure is especially advisable when assistance is scarce and sterilization uncertain. With the patient in the dorsal position and under anesthesia the vulva and vagina are cleansed. A gauze pack is placed in the vagina to keep the field clear of blood. Perineal sutures may be inserted while waiting for separation of the placenta but should not be tied before the uterus is emptied. The first suture is placed high in the vagina to catch the high levator fibers and each succeeding suture is placed a little lower. For perineal repair the right vulvar tissues are retracted and the needle is inserted on the left side of the vagina its point swept well laterally and posteriorly toward the spine of the ischium so as to secure a good wide bite of the left levator ani fibers then avoiding the rectum one brings the needle medially and finally anteriorly out through the mucosa. The needle is reinserted at the hole made by its exit. The point is kept just under the mucosa and brought across to the right side of the vagina and out and the needle is reinserted at the point of its exit and directed laterally and posteriorly, then medially and anteriorly, to encircle the right levator fibers and again brought out through the mucosa. At its last point of exit the needle is reinserted kept just under the mucosa and brought back across the vagina to the first point of insertion and out. The suture ends have now been brought together. Holding them taut with a hemostat, to keep the levator fibers together simplifies the insertion of the next suture. Before the sutures are tied, the perineum is relaxed by removing the vaginal pack and retractor and further extending the thighs. A finger is inserted into the rectum to feel for sutures and remove any that have penetrated. The sutures are tied from above downward snugly enough to coapt muscle and fascia but should not be pulled tight. The levator fibers of both sides are thus brought together between the rectum and vagina. The suture ends are cut at least one-fourth inch from the knot. After the repair has been completed the perineum is palpated to make certain that the united levator fibers may be felt as a firm, thick mass of muscle. When the mucous membrane is torn or after episiotomy, repair is completed in much the same manner except that the muscles may be more easily reached.

through mucosal openings. When the muscles have been sutured, the mucosa may be closed by the usual means.

Reduction of Fractures of Radius—Clark found that the most serviceable thing to use in reducing fractures of the lower end of the radius is a roller about 1 inch in diameter and 5 inches long, the ends being smaller than the middle so that it can be conveniently handled. With this simple instrument the force can be accurately placed and easily controlled. The patient should be lying down with the broken arm on a firm table. Adequate anesthesia is essential. The arm is laid palm down over a triangular wooden block which serves as a fulcrum under the anterior aspect of the radius about 2 cm proximal to the fracture. The assistant holds the elbow down firmly against the table and if there is excessive posterior displacement of the distal fragment he also holds the hand in hyperextension at the wrist. The operator, facing proximally with relation to the arm, places the roller across the dorsal aspect of the radius at a right angle to the shaft, just above the distal fragment. With one hand on each side of the patient's wrist the operator's thumbs are hooked over the handle of the roller. Firm pressure is made so that the roller is felt to be right down on the bone. This pressure is maintained as the instrument is rolled distally against the distal fragment. It first impinges on the posterior corner of this fragment the force thus being in a distal direction with relation to the fragment. As the roller continues on toward the wrist the force changes gradually from distal to anterior thus pushing the fragment into the normal position. This rolling process usually has to be repeated several times. If palpable deformity persists more force in the anterior direction should reduce it. Fractures of both radius and ulna from 3 to 5 cm above the wrist with complete posterior displacement and overriding of the distal fragment can be reduced by the roller method. For immobilization after reduction, anteroposterior wood splints are best. They can be accurately applied with felt pads to produce pressure at the proper places over the fragments. They also permit easy inspection of the skin for possible pressure sores.

Weight Taking in Prenatal Care—Harding and Van Wyck believe that gains up to 5 pounds (2.3 Kg.) a month in pregnancy can be considered normal. It will be rare to find toxemias developing in this group. Gains from 5 to 8 pounds (2.3 to 3.6 Kg.) a month should be regarded with suspicion. Such patients should be placed on a salt-poor diet and restricted in caloric intake. They should be watched more closely than the strictly normal woman. Gains of 8 pounds and more a month indicate a potential toxemia. The closest supervision should be exercised over such patients. The gains in weight have preceded the more usual signs of toxemia, i.e. albuminuria, edema and hyperpnea. If water retention can be prevented or controlled, the toxic process may be averted. The small number of toxemias in this series (about 1 per cent) justifies the practice of weight taking in prenatal care. Although definite signs of toxemia developed in a few cases not exhibiting convulsions the maternal mortality was zero. In view of their observations the authors urge every obstetrician and general practitioner to practice weight taking during pregnancy. The

use of scales should be general in every maternity and prenatal clinic. The taking and charting of the weight involves no expensive equipment or laboratory training. This duty could well be carried out by the nurse in charge, who would report any gains considered excessive.

Allergic Relations of Floras of Intestine—Benson states that the pathogenic gram positive cocci found in stool culture of asthmatic patients and other allergic subjects behave as allergens. Their action combines in varying degrees type specificity and species specificity. A bacterial allergen of the latter nature is reported. The group specificity of normal flora bacteria was studied and certain properties of the antigens are described. It is the author's belief that alterations in the integrity of the colonic mucosa make possible the absorption of products of the ordinary pathogens and likewise of the so called normal flora. The behavior of the two differs in marked degree but both must be considered as possible allergic factors in nonseasonal cases.

Drinking Water as a Cause of Asthma—Watson and Kubler report a case in which it was proved that drinking water was the cause of asthma and so called functional colitis. It is generally known that the chlorine radical of sodium hypochlorite is the effective part in making water safe for drinking. The sodium is inert. It therefore seems reasonable to believe that it was the chlorine radical which was responsible for the asthma in this case and not the sodium. As further corroboration

ration, the patient salts his food with sodium chloride and can take sodium bicarbonate without untoward effect. It seems possible, in view of this particular experience, that chlorine in drinking water may be the cause of persistent residual symptoms in a certain number of allergic patients not otherwise relieved by the present day rather exhaustive methods of treatment.

Blood Gas Analysis.—By modifying the reagent used in the Van Slyke method for blood gas analysis, Rappaport and Kock-Molnar have found a way to avoid the clotting without making the analysis more difficult. Their reagent consists of 3.3 Gm. of potassium ferricyanide, 3.3 Gm. of saponin, 450 Gm. of urea, 5 cc. of octyl alcohol and enough distilled water to make 1,000 cc. The necessary quantity of lactic acid (0.66 cc. of normal lactic acid to 6 cc. of reagent) is put into the cup of the apparatus immediately before the reagent is made air free by evacuation. The authors state that this reagent may be used for macro analyses and micro-analyses of all blood gases in one sample and for the determination of carbon monoxide in the blood after the absorption of the oxygen with pyrogallol or hydrosulphite. They also succeeded in performing oxygen and carbon dioxide analyses in Van Slyke's volumetric micro-apparatus. Their analyses agreed exactly with those performed with the original reagent.

Similarities Between Experimental Scurvy Combined with Infection and Rheumatic Fever.—Rinehart and his associates observed that in the guinea-pig chronic scurvy with superimposed infection (beta streptococcus) and to a lesser extent chronic scurvy alone produces an arthropathy with striking pathologic similarities to that of rheumatic fever and the

closely allied condition of rheumatoid arthritis. Considerable significance is attached to the widespread occurrence in the experimental animal subjected to scurvy and infection, and to a lesser extent in scurvy alone, of lesions similar to if not identical with the fibrinoid degeneration that has been considered the fundamental lesion of rheumatic fever. A subcutaneous nodule essentially similar to the subcutaneous nodules of rheumatic fever was observed in one experimental animal. The authors call attention to a group of general pathologic changes frequently observed in rheumatic fever, which were also found in the experimental animals subjected to scurvy and infection. These include degenerative changes in skeletal muscle, focal necrosis in the liver, fibrosis of the malpighian bodies in the spleen, erythrophagocytosis in the lymph nodes and focal lymphocytic accumulations in the kidneys. They consider the problem of hemorrhage and suggest that a scorbutic state may be the basis of the hemorrhagic manifestations common to the acute phases of rheumatic fever. The unsatisfactory nature of previous experimental attempts to reproduce the pathologic changes of rheumatic fever is noted. The lesions produced by subjecting the guinea-pig to the combined influence of scurvy and infection are considered to be fundamentally similar in character and distribution to those of rheumatic fever. The pathologic observations recorded in this and a previous report are believed to offer evidence that the disease known as rheumatic fever may be the result of the combined influence of scurvy and infection. A subclinical degree of scurvy may constitute the rheumatic tendency in which the added factor of infection causes the development of rheumatic fever or possibly the closely allied condition of rheumatoid arthritis. Epidemiologic and clinical considerations appear to afford supportive evidence to this concept.

- Depression of Phagocytosis by Products of Staphylococci R. M. Pike—p. 69

Localization and Fate of Bacteria in Tissues.—Sullivan and his associates observed that living staphylococci and paratyphoid bacilli injected intravenously into rabbits are quickly removed from the circulating blood stream and are localized particularly in the liver and spleen, where they are ingested and destroyed by phagocytes. The lungs, bone marrow and omentum remove distinctly fewer numbers, and such organs as the kidney, suprarenal, striated muscle, brain, testicle and thyroid remove negligible numbers under comparable conditions. In other words, the primary localization occurs principally in the two organs containing many macrophages and a sinusoid type of blood flow, whereas practically no localization occurs in organs poorly supplied with macrophages and with a rapid blood flow through vessels lined with ordinary endothelium. Active immunization does not significantly affect the comparative degrees of localization for different organs of the same animal, although it leads to a more energetic removal of the bacteria from the blood stream by the liver and spleen. Bacteria are concentrated more quickly in the liver and spleen of immune than of normal animals but are also killed more rapidly within these organs. Active intravenous immunization leads to a stimulation of mesenchymal tissues, particularly in the liver and spleen, with a resulting elevation of the functional state of the system of macrophages.

The Age of Choice for Operations of Choice in Infancy and Childhood T H Lanman, Boston—p 107

Management of Juvenile Diabetes—Bader chooses diets for feeding diabetic children as nearly similar to the diets fed normal children as possible. They are high in carbohydrates and low in fats. From 2 to 3 Gm of protein per kilogram of body weight is allowed unless the child is considerably underweight and undersized. An equal number of fat grams is given. The remainder of the total calories required is furnished as carbohydrates. The question of the amount of food in calories to be given to a particular diabetic child varies as in the normal child according to its individual needs. One must be guided by the child's response in growth and gain in weight. The advantages of such a diet are described. At least two daily doses of insulin are required, one before breakfast and the other before supper. Sometimes three daily doses of insulin are advantageous. A third dose of insulin has an economic advantage, because it reduces the total insulin required for twenty-four hours. It also reduces perceptibly the amount of insulin necessary per dose and thus reduces the likelihood and frequency, as well as the severity, of insulin reactions. A detailed account is given of a diabetic child on such a regimen. It includes a method of computing the diet and the insulin, the manner of dividing the diet and the insulin, a technique for desugarizing and stabilizing, and subsequent care. The importance of proper diabetic control is emphasized because it is the uncontrolled diabetic child who does not thrive.

Value of Lateral Pyelograms in Urologic Diagnosis—Mertz and Hamer state that lateral pyelography is practical and can be easily performed on the ordinary x-ray cystoscopic table without added discomfort or risk to the patient. The renal pelvis and ureter can be satisfactorily visualized in the majority of cases. A study of the lateral pyelogram should include the vertical and anterior position of the kidney, the degree of horizontal and vertical rotation of the kidney, the outline of the pelvis as compared to that in the anteroposterior pyelogram and the course followed by the ureter. The authors' cases have been too few to establish general rules of interpretation, yet they feel that their experience is sufficient to justify a general report.

Neosarsphenamine Treatment of Intestinal Protozoal Diseases in Man with Especial Reference to Amebic Dysentery W I Chandler Lansing—p 27

Neosarsphenamine Treatment of Intestinal Protozoal Diseases—Chandler treated several hundred infections involving eleven different species of intestinal protozoa of man with three intravenous injections of from 0.6 to 0.9 Gm of neosarsphenamine at intervals of five days. He presents protocols of seventeen cases of amebic dysentery, in all of which the organism was absent after three injections of neosarsphenamine. Two of these cases were observed over a period of ten years, during which time six stool examinations in one case and ten in the other one showed no *Endamoeba dysenteriae* organisms. The author believes that these organisms are more easily eliminated from the digestive tract by the use of intravenous injections of neosarsphenamine than some of the other intestinal protozoa. In the initial experiments on this organism, 0.6 Gm was used as a standard dose. Other organisms, especially the trichomonads and spirochetes, required as much as 0.9 Gm to bring about their complete elimination. Since the microscopic examination of a single stool or even the examination of a series of stools may fail to reveal all the intestinal protozoa that may be present in any given case, a maximal dose (0.9 Gm in the case of men and 0.75 in women patients) has been used by the author in all intestinal protozoal infections for the past thirteen years. Following the intravenous injection of 0.6 Gm of neosarsphenamine, the organisms were absent from the third consecutive stool. Often these were not found in the second stool. In one case in which 0.3 Gm was injected the organisms were absent from the second and third stools following the injection and from three consecutive stools examined one month after the injection but were found in stools examined nine months after the injection. In subsequent treatment three injections of 0.6 Gm were given at intervals of five days. No organisms were found in stools examined at intervals for several years. These seventeen cases represent data of the initial experimental cases. During the past fourteen years he has treated a large number of cases with three intravenous injections of from 0.6 to 0.9 Gm of neosarsphenamine. Symptoms rapidly disappeared, even in cases of liver abscesses and arthritis.

The Association of Diabetes and Tuberculosis—Root states that, in order to promote good nutrition and resistance to tuberculosis, the use of insulin should be begun immediately in all youthful diabetic patients. Considering age, weight and diet, the tuberculous diabetic patient requires about the same dose of insulin as the nontuberculous patient. The average daily dose in eighteen cases of tuberculosis and diabetes (between the ages of 15 and 29 years) was 39 units. Serious hypoglycemia must be guarded against by the cautious use of insulin in severely ill or emaciated tuberculous diabetic subjects. In sixty-nine fatal cases of tuberculosis and diabetes treated with insulin the patients lived 86 years, whereas in ninety fatal cases treated without insulin the patients lived only 54 years after the onset of diabetes. In the last ten cases of active tuberculosis and diabetes with fever, an average diet of 157 Gm of carbohydrate, 83 Gm of protein and 116 Gm of fat, totaling 2,004 calories, and 42 units of insulin were administered. Patients suffering from acidosis and coma who later develop tuberculosis should be followed up yearly by roentgen examination for the detection of developing tuberculosis. Eighteen patients alive in 1933 have survived active pulmonary tuberculosis for an average of nine years. The recognition of pulmonary tuberculosis in a truly incipient stage in a diabetic patient is almost unknown in the literature. Ten cases occurred among 245 in the author's series. Prognosis for the tuberculous diabetic subject depends on earlier diagnosis of the tuberculosis by more frequent physical and roentgen examination. The modern prolongation of life of the diabetic patient and his greater entrance into general activities expose him to tuberculosis and may result in a greater incidence of tuberculosis among diabetic patients. Uncontrolled diabetes increases the chance of developing tuberculosis, as indicated by the development of tuberculosis in persons who have had coma. Preventive measures include early diabetic treatment and hygiene.

Etiologic Factors of Mammary Cancer—Adair studied 200 cases of cancer of the breast with the idea of evaluating the various factors of breast drainage and stagnation. Chemical analysis is made of the fluid and creamy material extracted from the breast by pumping. In these fluids both lactic and butyric acids are found. These acids are considered to be an important part of those irritating factors responsible for the tissue reactions resulting in hypertrophy, precancerous changes and eventually cancer. The breasts are pumped in order to abolish localized mastitis. Only 85 per cent of the cases in which mammary carcinoma developed gave a normal nursing history, a history entirely free from the various developmental or accidental incidents leading to at least one and sometimes two three or more of the various factors causing impaired drainage. In this cancer group every third pregnancy ended in miscarriage or abortion while in the control cases of 100 normal women there was only one miscarriage or abortion for every seven pregnancies. Of the women having cancer and bearing children 20 per cent nursed only a part of the children and 16 per cent did not nurse their children at all. Of the seventy eight mothers in the 100 control cases, sixty two gave a normal history of nursing. The clinical studies agree with the experimental studies of Baggs who produced artificial stagnation by breeding experiments and by ligating the nipples of the breasts.

Value of Tetrachlorethylene in Hookworm Disease—According to Garrison, statistics from laboratories of departments of health of the South from physicians in private practice and from other well known authorities would indicate that although the percentage of hookworm infestation has been greatly reduced in the last twenty years it is evident that hookworm is still prevalent. The results obtained with tetrachlorethylene as compared with those of oil of chenopodium and carbon tetrachloride by all who have had an opportunity to make any comparison even under field conditions would indicate the absolute superiority of tetrachlorethylene. Studies of the pharmacology, toxicology and therapeutic effects of tetrachlorethylene indicate that it is the safest most economical and best known treatment for hookworm disease.

Use of Plasmochin in Malaria—Hayden gave follow-up treatment to 125 men having histories of recent acute malaria. Seventy two were given quinine alone, 10 grains (0.65 Gm) daily except Sunday for a period of eight weeks. Of these, seventeen men, 23.6 per cent, had acute recurrence of their malaria either toward the end of their period of follow-up treatment or shortly after its completion. The remaining fifty-three men were given follow-up treatment of quinine and plasmochin. This treatment consisted of 10 grains of quinine daily for three weeks and 0.02 Gm of plasmochin daily for six consecutive days each week for the first and second weeks of this treatment. Of the fifty-three men, only three had relapses, 5.6 per cent. The malarial infections were of various types—tertian, quartan, malignant tertian and mixed. In view of his experience in this respect at Quantico and of reports from other places on the same subject the author is of the opinion that plasmochin should be regarded as an essential part of postmalarial follow-up treatment and should be administered in combination with quinine.

Necrobacillo is—Shaw emphasizes the fact that necrobacillo is is a disease widespread in nature and that only a few infections have been reported in man but these have been of such a variety of clinical manifestations and geographic distribution as to lead one to infer that the disease is of more common occurrence than the reports would indicate. The difficulty of isolation of anaerobes in general and of Actinomyces necrophorus in particular is probably responsible for the low record. Few anaerobic cultures are made in general. From Cunningham's report anaerobic cultures should be made of blood in all cases of infectious jaundice. Some of the tuberculous hips are in all probability, necrophorus infections. The treatment of necrobacillo is is local and systemic—potassium iodide (or arphenamine in van Wiering's case) internally and the use of antiseptics in the cutaneous cases.

Diathermy in Treatment of Pneumonia—Stewart believes that the patient who does not respond favorably in any clinical sign after three or four diathermy treatments presents an almost fatal prognosis. Large increase in diathermy dosage is indicated when the patient is improved temporarily by treatment. No other indicated measure in the treatment of the disease need be omitted because of the use of diathermy. It is one of the safest measures known to medical practice, as far as is known no accident or untoward effect has followed the administration of some 20,000 individual treatments. The use of diathermy in pneumonia is advocated by all who have had an opportunity for clinical study of its effects. The method has a sound physiologic basis, gives the patient a measure of relief which alone would justify its use, reduces the average mortality some 70 per cent and is well worth further clinical application and study.

*Improved Technique for Examination of the Shoulder. J. N. Ierfusson—p. 33

Roentgen Examination of the Shoulder—Ierfusson describes a technique for obtaining a lateral view of the shoulder. The patient is placed supine on the Potter-Bucky diaphragm and the sound shoulder is elevated by pads so as to cause 30 or 40 degrees of rotation of the body. The head is supported by a cushion and turned sideways toward the damaged side, which brings the scapula forward and more nearly parallel with the film. The curved type of Potter-Bucky diaphragm has advantages for this work. The film must be suitably decentered. The patient is now helped to turn over and to lie nearly prone with the sound shoulder elevated and the damaged one in contact with the diaphragm top. In this instance it is allowed to slide a little to one side of the center line. The scapula is inclined slightly from the vertical angle and in the path of the oblique ray. Judgment of the correct angle comes with experience. It helps if the arm can lie along the side of the chest and somewhat behind. This oblique prone position sounds uncomfortable, but many patients manage it. One of its advantages is that the body weight is utilized; it helps to keep the scapula a little way from the thorax. Muscular relaxation also helps. Sometimes the bone stands out like a wing. The author generally uses a kilovoltage of about 65 for the first position and 80 for the second. Some discrimination is required in selecting cases suitable for the positions described, especially the prone position.

Ossification in Internal Semilunar Cartilage—Burrows reports two cases of ossification in the internal semilunar cartilage. Histologic examination in the first case shows that the hard nodule contained bone. The fibrocartilage immediately surrounding this is in places clearly demarcated from the trabeculae, in other parts there is some tendency to a blending or transition. It shows patches of calcification and its cells are increased in number and hypertrophied. Many of them are surrounded by chondrin bills. While this tissue retains the essential characters of fibrocartilage, its appearance approximates that of hyaline cartilage. The portion immediately contiguous to the main nodule of bone contains spaces occupied by loose connective tissue and blood vessels. Some of these are surrounded or partly surrounded by a thin lamella of bone. Osteoclasts are inconspicuous. The sections suggest 1 Hyperplasia of the fibrocartilage with deposition of calcium, the cells multiply and enlarge and the proportion of matrix to fibers increases. 2 Replacement of areas of cartilage by loose vascular connective tissue. 3 Formation of true bone in the walls of the cavities so formed. The appearances in the other case resemble those in the first in that the fibrocartilage contiguous to the bone has undergone hyperplasia. They differ in that the vascular connective tissue spaces are relatively absent from the zone of hyperplastic cartilage. In parts the cells are particularly numerous and may tend to become arranged in rows at right angles to the zone of ossification. The nodule of bone contains several small islands of hyaline cartilage and there is a thin shell of this overlying a part of the surface. Both patients are young men who had received an injury at football a few years previously. Each had been troubled by a return of symptoms from time to time with apparent complete recovery in the intervals. Locking had been absent. Roentgenograms showed an opaque body of about the same size in about the same position (the postero-internal part of the patella) in each instance. These points might assist a correct preoperative diagnosis on another occasion and might be thought to justify an initial antero-internal incision, through which all that is required could be done. It would be much safer, however, as such a diagnosis must always be a tentative one to proceed in the manner customary for a loose body in the situation named. Whether an antero-internal incision should subsequently be made and the anterior part of the cartilage removed is a matter of opinion. As yet, it is too soon to know whether the fact that this step was omitted in the second case will give rise to trouble. The author prefers to do the more complete operation.

Hyperparathyroidism with Unusual Features—Mumpriss and Butler describe the occurrence of hyperparathyroidism with a parathyroid tumor and changes in the bones in a boy of 17 in whom growth is still taking place rapidly and in whom therefore the bone changes are somewhat atypical. The unusual roentgenographic appearance of a well defined transverse band

of increased density at the metaphyses as an early bone change is probably associated with the presence of active epiphyseal growth. This metaphyseal change does not appear to have been recorded as a manifestation of hyperparathyroidism with a parathyroid tumor, although Duken has reported similar changes and published reproductions of the roentgenograms in the case of a girl aged 14, diagnosed as late rickets which subsequently showed the changes of osteitis fibrosa. In his case the blood calcium showed a progressive rise and the plasma phosphorus was low, but at the time of reporting the case no suggestion had apparently been made of the presence of a parathyroid tumor. Another unusual feature of the authors' case is the failure of renal function with the progress of the disease, and its recovery on the removal of the tumor. This failure of renal function was not associated with the formation of renal calculi, which has frequently been recorded in hyperparathyroidism. No exact explanation of this failure can be put forward, but it is of interest to note that Hunter and Aub have reported a marked rise of the nonprotein nitrogen of the blood following the administration of large doses of parathyroid extract in human beings. The patient recovered completely after operation, in spite of his extremely precarious preoperative state. There are no permanent skeletal changes.

*Prognosis of Symptomless Glycosuria P J Cammidge—p 1208

Prognosis of Symptomless Glycosuria—According to Cammidge, the more thoroughly the family history of cases of glycosuria is investigated the more evident does it become that heredity plays an important part in the etiology of the condition, and it would seem probable that the way in which the abnormality is inherited as a familial or direct character, has some bearing on its severity and therefore on the prognosis. In a series of 800 cases of diabetes mellitus, 28 per cent were found to give an ancestral or family history of the disease, but in the present series the proportion is 38 per cent taking the cases of classic diabetes alone or, including the cases of symptomless glycosuria 36.5 per cent. Considering the 420 cases of symptomless glycosuria separately a history of glycosuria in a blood relation was obtained in 142 (33 per cent). Of the 248 who showed a hyperglycemic curve after a test meal of dextrose, 88 (35 per cent) gave a family history of glycosuria while a positive history was obtained in 54 out of 172 (31 per cent) of those who gave a normal or subnormal blood sugar curve. A dominant or direct history was found in 126 (16 per cent) and a recessive or familial history in 171 (22 per cent) of the classic diabetic cases but in the symptomless glycosurias there were 124 (29 per cent) dominant and only eighteen (4 per cent) recessive. Of the eighteen symptomless cases with a recessive family history fifteen were of the severe persistent type and gave a hyperglycemic curve after a test meal of dextrose. All required treatment with insulin—although not until after the lapse of some years in most instances—and two patients have died, one from malignant disease of the colon twenty-two years later, and the other from heart disease after six years treatment. The other three gave hypoglycemic blood sugar curves with a moderate amount of urinary sugar and are now living normal lives.

Ovulation and Menstruation—Shaw attempted to observe the relation between ovulation and menstruation in women who menstruate regularly with a normal rhythm and has shown in

other reports that irregular bleeding is characterized by departures from the normal relations. The time relations of ovulation and menstruation have been reinvestigated with the use of the method of identifying recently ruptured follicles in the ovaries of women who give reliable histories. It has been shown that ovulation is restricted to about the fourteenth day of the cycle. There is some variation in the time of ovulation, but the variation is probably not more than two days from the fourteenth day. A study of the condition of the corpora lutea at other stages of the cycle confirms this view. Indirect proof as to the time of ovulation can also be obtained by an examination of specimens of the endometrium of the uterus. It has been shown that the secretory phase of the endometrium develops after the fourteenth day of the cycle. The specific features of the secretory phase are never seen before the fourteenth day. Seventeen specimens of the menstruating endometrium have been examined. In all cases there was evidence of previous premenstrual hypertrophy. In the material examined, no parallel was found to the anovular cyclic bleeding of the macaque monkey.

*Laboratory Diagnosis of Enteric Infection Remarks on Persistence of Infection A W Downie and R W Fairbrother—p 55

*Collapse Therapy in Bronchiectasis A Warning H P Nelson—p 58

Laboratory Diagnosis of Typhoid Infection—Downie and Fairbrother emphasize that, toward the end of the first week examination of the blood by cultural methods and agglutination tests with the serum will in the majority of cases afford evidence of the nature of the disease. The evidence obtained by the agglutination test should be confirmed by isolation of the infecting organism from the feces or urine whenever possible. Later in the course of the illness agglutination tests with the patient's serum generally give more marked reactions and while blood cultures are less frequently positive, the isolation of the causal organism from the urine and feces is more readily effected especially during the second and third weeks. In the detection of carriers, examination during convalescence is of the utmost importance. The carrier state may be merely temporary, the organisms being excreted for some weeks or months after the febrile period. Such cases tend to clear up spontaneously but, in order to prevent the spread of infection from these adequate methods of testing for freedom from infection during convalescence must be employed. At least three successive negative reports on feces and urine should be received at weekly or fortnightly intervals before a person can be considered probably free from infection. In the permanent carrier excretion of the organisms in feces or urine, sometimes intermittent, persists indefinitely and this presents a much more difficult problem. The only satisfactory method for removing the source of infection appears to be operation.

Collapse Therapy in Bronchiectasis—Nelson cites two cases that demonstrate the point that, when collapse therapy is applied to cases of bronchiectasis, it must be appreciated that such therapy may exclude the possibility of a subsequent lobectomy, should it become necessary. After a phrenic division for a basal bronchiectasis there may be a temporary improvement but subsequently, when the diaphragm has completely atrophied the patients return to the same or a worse condition. Artificial pneumothorax frequently fails owing to extensive pleural adhesions but when a complete collapse is obtained the symptoms may disappear as in the cases quoted by Chandler and referred to by Beaumont in the *British Medical Journal* of Oct 14, 1933. Thoracoplasty for basal bronchiectasis has on the whole given extremely bad results and involves the sacrifice of a whole lung for a basal lesion which is obviously wrong. But this operation still has a place in the treatment of unilateral bronchiectasis when all the lobes are grossly affected and there is a large quantity of sputum. By means of an extensive resection it is possible to reduce the sputum in these cases from say 20 ounces to 1 or 2 ounces occasionally they may even be sputum free but in the majority it recurs again—although never of course to the same extent as before operation. Thus the choice of therapy in basal bronchiectasis seems to be between (1) posture and bronchoscopy and (2) lobectomy with a mortality of 8 to 10 per cent.

Clinical Studies in Pathology of Bone D. M. Greig—p. 43

Suprarenogenital Syndrome—Foggie and Montgomery report the case of a woman of 36 who became gradually changed in both physical and mental characteristics after the birth of a stillborn child. Adiposity, hirsuties and amenorrhea with added pigmentation became evident. Further, there was a change in her voice. At first there was an overactivity of body and mind with special mental and psychosexual phenomena, but later there was a physical wasting with marked mental degeneration before complete dissolution set in. The whole process lasted two and a half years. Pathologically there was bilateral hyperplasia in the cortices of the suprarenals with some adenomatous formations. There was also advanced renal sclerosis of vascular origin. The clinical picture represented the assemblage of symptoms that directs attention to the suprarenal. Apart from the underlying cause this patient exhibited what is recognized as the corticogenital or suprarenogenital syndrome. Cook was one of the first to associate such a condition with a lesion of the suprarenal cortex, while Apert and Gillis did much to help in the elucidation of the clinical side. It is now recognized that there are various types of this condition: embryonic with resulting hermaphroditism, early life with precocity, exaggerated muscularity and secondary sex characteristics, puberty and after with adiposity and secondary sex phenomena, occurring especially in women and associated with the reproductive period of life and postmenstrual type, with less marked changes. The present case belongs to the third group and is marked by all the signs and symptoms usually associated with it. The three cardinal signs are amenorrhea or, better, sexual dystrophy, as men may be affected, hypertrichosis and adiposity. In the present case menstruation was irregular at first, but there was amenorrhea for the last six months of the patient's life. The pathologic evidence was not considered conclusive as the suprarenal lesion did not appear to be sufficient to account for the gross changes that occurred and the case had obviously many points of resemblance with the bronchial type described by Cushing, but in the absence of a report on the hypophysis one can only leave the final diagnosis an open one. Such a case with pluriglandular suggestion would be unlikely to benefit by operative treatment directed to the suprarenal. If Cushing is right in his generalization the logical thing would be to concentrate on the hypophysis either by operation or by roentgen therapy. In some cases of suprarenal tumors of local origin, roentgen therapy has been reported as beneficial.

Untreated Malaria—Lowe made a study of thirty-seven untreated cases of malaria due to fresh (but probably not primary) infection with *Plasmodium vivax*. Twenty-seven of them showed a quotidian intermittent fever. The rigors occurred usually after midday. Relapsed cases showed a tertian intermittent fever. The quotidian fever in fresh infections is found to be due to the parasites maturing in two main crops on alternate days. Most of the observations of James (1926) in experimentally induced malaria are verified in this series of cases of naturally acquired malaria. Eleven cases kept entirely

without quinine showed spontaneous arrest or fever within two weeks, and in only two of these was there a relapse, these relapses subsided spontaneously. The author also observed twenty-one cases of malaria due to fresh (but probably not primary) infection with *Plasmodium falciparum*. In eight quinine was withheld for a time. Four of these showed a quotidian remittent fever and four showed a tertian remittent fever. The fever was not intermittent, because there was some sporulation of the parasites occurring all the time, but in addition there was sporulation of either one or two main crops of parasites about midday, causing either a tertian or a quotidian periodicity.

Poisoning by Barbituric Acid Compounds—Purves Stewart and Wilcox state that barbituric acid compounds after administration are excreted rapidly in the urine (with the exception of dial, much of which appears to undergo decomposition in the body). They are found in appreciable quantities in the cerebrospinal fluid. In the treatment of poisoning by barbituric acid compounds, every effort should be made to hasten elimination of the poison from the body, thus the stomach should be washed out with warm water immediately and this may be repeated at intervals of from four to six hours for two or three times. Colon lavage should be given at once and repeated every twelve hours for two or three times. Since the coma is prolonged, food should be given by stomach tube at intervals of six hours, e.g., coffee, dextrose and peptonized milk in quantities of from 15 to 20 ounces. From 15 to 20 ounces of saline solution and dextrose should be given by rectum every twelve hours. Repeated hypodermic injections of strychnine in full doses are also valuable. Lumbar or cisternal puncture and drainage are carried out at intervals of from twelve to twenty-four hours, according to the symptoms and severity of the case. The application of cerebrospinal drainage removes the poison directly from the brain, on which the main toxic effect is manifested. Rapid improvement is frequently observed after each drainage as shown by return of the tendon reflexes and improvement in the general symptoms. Cerebrospinal drainage appears to be the only form of treatment that gives a hope of recovery when pneumonia (barbital pneumonia) has commenced.

Head Injury Causing Auricular Fibrillation—Bramwell reports a case in which auricular fibrillation appeared to have been produced by an injury to the head in an otherwise healthy young coal miner. Though the evidence in this particular case strongly suggests that the arrhythmia was due to the trauma the fact that such a relation has not previously been reported makes one hesitate to accept this hypothesis. The fibrillation persisted for four weeks and then promptly yielded to treatment with quinine and has shown no tendency to recur. Although it is possible that fibrillation might be initiated by an injury to the brain, it is difficult to accept this hypothesis in view of the strong circumstantial evidence to the contrary. Jefferson states that in a series of several hundred head injuries he has never encountered auricular fibrillation as an isolated phenomenon. Nor is tachycardia a recognized sequel to such injuries, though occasionally it does occur.

Diagnosis of Meningitis from Spinal Fluid—Macgrath remarks that the laboratory diagnosis of meningococcal meningitis from the examination of the spinal fluid can be performed in a few hours by the use of the precipitin or complement fixation tests. The causal organism can be typed by the precipitin method if strong monovalent serums are available. The growth of the isolated organism on immune serum agar plates may permit the early diagnosis of type I and III meningococci. Slide agglutination is sometimes of value in diagnosis. English monovalent serums are not satisfactory for the diagnosis of type by precipitation, and until better serums are available a combination of the polyvalent precipitin reaction and the growth of the organism on immune serum agar plates seems to be the quickest method of diagnosis of meningococcal infections from the examination of spinal fluids.

Complete Closure of Bladder in Suprapubic Prostatectomy—Whitby describes a method, more especially for prostatectomy, whereby he believes that the bladder can be closed with safety at the operation. When renal function tests are poor or there is any form of infection of the bladder, drainage by a two way catheter and continuous irrigation with 1:5000 silver nitrate solution at 110 F for a few days or longer is essential to the success of the operation. The reduction of the blood urea will be further assisted by an intravenous injection of 40 cc. of a 25 per cent solution of dextrose in saline solution. The two-way catheter, of a size to suit the urethra is soaked in petrolatum and inserted into the bladder through the urethra. Continuous full irrigation is carried out for a few minutes with a solution of 1:8000 silver nitrate at body temperature, until the bladder is clean. The bladder is allowed to fill with the same solution and the outlet and inlet of the catheter are clamped. The patient is placed in a slight Trendelenburg position. As soon as the bladder incision is made the assistant drains the bladder through the outlet of the catheter. The prostatic cavity is viewed. Hemorrhage is dealt with by ligation of all bleeding points, and two ligatures are passed through the mucous membrane of the bladder and the sphincter, passing out through the prostatic cavity one on each side of the midline. The edges of the cavity are trimmed and a continuous ligature is passed round the edges. At this stage if the anesthetist gives the patient pure oxygen for a few minutes any obvious bleeding points requiring ligation will be seen. Ordinary venous oozing can be coagulated by light diathermy for a few seconds at about 7 milliamperes with a suitable electrode. After this a swab soaked in pure glycerin can be pressed into the cavity for a few moments which will check evadation. The bladder is completely closed and then irrigated until the return fluid is clear with hot silver nitrate solution of 1:5000 through the two way catheter which is

arranged so that the two terminal eyelets lie in the bladder cavity and the other eyelet in the prostatic cavity. Some of the solution is left in the bladder and the catheter is clamped until the patient returns to the ward, where continuous irrigation is instituted with a thermoflask retainer. The catheter is held in position by a collodion dressing round the entire penis, and this dressing should not require to be removed until the catheter is ready for removal. The projecting portion of the catheter should be cleansed with an antiseptic daily. Pain and sleeplessness should be relieved by means other than morphine. The head of the bed should be raised on blocks. Injection of 40 cc of a 25 per cent solution of dextrose in saline solution is given intravenously and repeated every six hours if necessary. Drainage should be inspected every half hour to see that it is effective and that the bladder is not filling too quickly. The rate of flow should be about 8 cc a minute. The catheter should be removed on the tenth day and reinserted only if the patient does not pass urine satisfactorily. A medium sized bougie should always be passed later to prevent postoperative stricture.

Diet and Endocrine Deficiency—Gardiner-Hill believes that a close relationship exists between dietetic problems and endocrine deficiency. This is well illustrated by observations on iodine in simple goiter, and vitamin A deficiency in lymphadenoid goiter. Calcium supplies, vitamin D and parathyroid extract are intimately associated in the metabolism of calcium while insulin is the controlling factor in carbohydrate metabolism. In some instances obesity and cachexia are due to endocrine deficiency, though the part played by diet in these conditions is at least equally important. As regards general principles of treatment of the series of conditions under consideration, the essentials seem to be replacement of the defective glandular secretion, with reorganization of the metabolic disturbance by appropriate dietetic measures.

Ayerza's Disease—Cristex and Capdehourat believe that the morbid alterations in Ayerza's disease can be divided into fundamental and accessory lesions. They consider as the fundamental ones all the chronic changes of the respiratory apparatus resulting from long continued bronchitis with or without peribronchial sclerosis and bronchiectasis, loss of elasticity and pulmonary fibrosclerosis, and chronic emphysema. The accessory lesions are those which do not enter actively into the development of the disease. Long continued bronchitis is, then, the prime factor in the development of the disease. Sclerosis of the pulmonary artery may or may not be present. Sclerotic lesions of the vessels of the lesser circulation, however, play an important part in increasing the work of the heart. Persons in whom the hemtopoietic system is incapable of reacting to the chronic bronchopulmonic process and anoxemia cannot develop the clinical picture of Ayerza's disease. This explains why the disease usually begins in youth, is less frequently seen in adult life, and is rarely encountered in old age. It is also the reason why, in spite of the frequency of the occurrence of chronic bronchopulmonic processes in old age, the pathologic picture of Ayerza's disease is so rarely seen.

Hemato-Encephalic Barrier in Nursing—Pincherle and Salom review the total literature on the blood-cerebrospinal fluid barrier, with especial reference to its function in early infancy. The authors have studied the permeability of the barrier to acid fuchsin in fifty-six infants not older than 13 months. They found that permeability was present in all cases in the first three months of life; it decreased during the next six months, until at the end of the first year the barrier acts as in adults. The authors maintain that the increased physiologic permeability of the barrier is probably due to immaturity of the anatomic elements at birth. They think that this permeability does not produce the tendency of infants to convulsions and to meningitis but that it may be one of the causes of alteration of the cerebrospinal fluid in congenital syphilis and of cerebral complications in intestinal intoxication.

Painful Spot in Shoulder in Acute Malaria—Pareja Coronel states that the presence of a painful spot in front of the scapula muscle corresponding to the area of the right phrenic nerve, is a diagnostic sign of acute malaria. The pain may coexist (although with less frequency and less intensity) in the left shoulder. In the blood of patients having this sign, *Plasmodium praecox* is usually found. The sign is characteristic of the first acute malarial infection. Patients with chronic or recurrent malaria do not present it. The author believes that the pain is a reflex manifestation of the hepatosplenic syndrome of acute malaria. Fifteen cases of acute malaria in which the sign was observed are reported.

Intussusception and Intra-Abdominal Pressure in Childhood—Ohndorck believes that sudden increase in the intra-abdominal pressure is in many instances the determining factor in intussusception of children. He reports a case in a girl who suffered from colicky pains about the navel for some time and in whom severe symptoms of invagination followed immediately a fit of severe paroxysmal cough. In a second case, symptoms of invagination followed straining at stool. At operation in this case there were found polyps in the small intestine. In both cases local spasms were present but appeared in themselves insufficient to cause intussusception. This was precipitated by a sudden increase in the intra-abdominal pressure. A local spasm of the intestine causes pain, which provokes in a child a fit of crying, which in its turn increases the intra-abdominal pressure. The latter may be of accidental nature, resulting from straining at stool, coughing or trauma. The author explains his failure to produce experimental invagination in animals by the absence in them of the factor of considerable intra-abdominal pressure. The peculiar predilection to invagination, so far as the age, the sex and the state of muscular development are concerned, is best explained by the part played by the intra-abdominal pressure.

Ventricular Ulcers in Patients with Leprosy A Faldorck —p 241

Spirochete Vaccine in Treatment of Syphilis—That the immunotherapy has been given so little attention Neuber ascribes to two factors: (1) the difficulties encountered in the culture of *Spirochaeta pallida* and (2) the progress in chemotherapy. The first factor has been overcome by Hilgermann who, after years of effort has succeeded in finding a way to put *Spirochaeta pallida* through several passages, reduce its pathogenicity and even produce avirulent spirochetes that are suitable for active immunization. In the author's clinic, 215 syphilitic patients were treated with Hilgermann's spirochete vaccine. Forty-two were treated in the beginning only with the vaccine (three times with intervals of two weeks), but in the further course the vaccinations were combined with injections of bismuth compounds and neoarsphenamine. In the other 173 patients the specific and chemotherapeutic treatments were combined from the beginning. The total number of vaccinations varied in different cases between one and ten; the majority of patients receiving three or four. The initial dose was generally 1 or 15 cc and this amount was gradually reduced to 0.1 cc and less. As a rule, the administration of the vaccine was done subcutaneously (upper arm), rarely intramuscularly, and only a few times intracutaneously. The reactions following the injections of vaccine usually became slighter after the later injections. Severe focal reactions were noted in fifty-six out of the 215 patients. General reactions were noted particularly after the larger doses of vaccine. The author reaches the conclusion that the treatment with spirochete vaccine influences the immunobiologic apparatus of the organism, but he thinks that in early syphilis it is not sufficient to free the organism from the spirochetes. He relates the results obtained with the vaccine in ninety-six cases of neurosyphilis. A comparison of the results in these cases with those obtained with malarial therapy or with recurrent fever therapy reveals that the vaccinations with spirochetes were superior in regard to complete remissions.

but inferior in regard to slighter improvements. The mortality rate was higher after treatment with the spirochetal vaccine, but this may be due to the fact that more of these patients were in an extremely weak and marantic condition. The number of progressive cases was larger after treatment with spirochetal vaccine than after malaria therapy, but only about half as large as after treatment with recurrent fever.

Etiology and Treatment of Acne Vulgaris—In fifty-two patients with acne vulgaris, von Kerner observed pyogenic foci, positive Pirquet reactions and pulmonary changes. Following removal of the pyogenic foci, the cutaneous changes disappeared spontaneously in twenty-two patients and in the others the pyogenic character suffered a surprising change. Thirty patients were subjected to tuberculin treatment following removal of the foci. The result was that twenty-seven were completely cured and two considerably improved, while one showed an exacerbation of the cutaneous symptoms. Other favorable effects noted in connection with the treatment were improvement of the appetite, increase in weight and cessation of gastro intestinal and menstrual disturbances. The author considers acne vulgaris a symptom of a combined tuberculous and pyogenic focal infection. He ascribes the chronicity of the disorder to the tuberculosis and the acute pyogenic eruptions to the internal pyogenic focus. The activity of the pulmonary foci is proved by auscultation, percussion and, eventually, roentgenoscopy, but cutaneous symptoms likewise may indicate it.

Cure of Botulism by Means of Antitoxin—Koehler relates the histories of two unusually severe cases of botulism, in which the first disease symptoms, disturbances of accommodation, were noticeable nine days before admission to the clinic. Both patients had been unable to sleep during eight nights. The oculomotor nerve was severely affected, particularly in the older patient. The vagus was involved as far as it innervates the pharynx, the larynx and the gastro intestinal tract, and the impairment of the muscles active in deglutition indicates involvement of the glossopharyngeal nerve. That important centers of the spinal cord were impaired was indicated by the cessation of salivation and of secretion of sweat, by ptosis in the smooth portion of the superior palpebral levator, by vesical disturbances, and by the temporary absence of the cremasteric and the abdominal reflexes. The sensorimotor paresis of the left side of the body (in the girl) indicated a unilateral involvement of the right cerebral cortex with its central convolutions. The two cases are noteworthy particularly because of the favorable and rapid action of botulism antitoxin. The action of the antitoxin serum was especially prompt in the girl in whom 100 cc, half of it intravenously and half intramuscularly was given at the first administration. Considerable improvement could be noted after half an hour for the left side of the body and the vision in the left eye improved and a beneficial warm sweat covered the body. The patient was again able to sleep, and on the following day she could swallow solid food. An additional 50 cc of the antitoxin serum was given by intramuscular injection on the subsequent day and as a result the function of the bowel became normal. Three weeks later the girl had completely recovered. The author deplores that in the older patient, the man, the initial dose of serum had not been sufficiently large for only 25 cc was given intravenously. He thinks that the cardiac complications could perhaps have been avoided if a larger dose had been given at once. This patient received in all 275 cc in the course of four days. After four weeks the patient was discharged completely cured except for a slight weakness in accommodation.

Complement Fixation Reaction in Gonorrhea—Saufferlin investigated whether the complement fixation reaction of gon-

orrhea can be made more sensitive by means of the quantitative evaluation combined with three different readings. The fact that in syphilis the evaluation with graduated amounts of serum may indicate slight inhibitions that are not perceptible with the original method induced the author to investigate whether the percentage of positive complement fixation reactions in gonorrhea can be increased by the same method. The evaluation upward is done in the usual manner with 0.3 cc and 0.5 cc of serum. The differentiated readings are taken the first after the dilution of the normal blood, the second twenty minutes later and the third after two hours. The author employed this method with 150 serums. He concludes that, in regard to diagnostic sensitivity, the quantitative evaluation is superior to the original method.

Diagnosis on Dried Cerebrospinal Fluid—The technic of the examination of the dried drop of cerebrospinal fluid, which Henning and Beck employ, is simple. After all formed elements have been removed from the fluid by means of filtration and centrifugation, a drop is put on a slide and is left to dry in an even temperature (incubator). Normal cerebrospinal fluid presents to the naked eye a fairly homogeneous, gray veil. Microscopy reveals peculiar sodium chloride skeletons, the configuration of which is characteristic for cerebrospinal fluid. Most typical is a cross figure formed by two beams that meet at an angle of approximately 90 degrees. The cross beams are rather plump and frequently oval the point of the egg being directed toward the center. The outlines are either smooth or serrated. Sometimes the beams are almost square so that the interstices are filled out. The size of the crosses varies according to their location in the circular preparation. In addition to these relatively large, plump and elevated formations there are also regularly rather delicate forms of plantlike appearance. The dry preparations of the normal fluid show no marginal zones, for the crystallization products begin immediately at the periphery. Since the preparations are hygroscopic they should be kept in closed containers with calcium chloride. The authors also examined pathologic specimens of cerebrospinal fluid and found that a slight increase in the protein content becomes manifest in a peripheral ring zone. The protein nature of this zone was demonstrated. The width of the ring zone goes parallel with the protein content. The widening of the marginal zone is accompanied by changes in the morphology of the crystallization figures. As the width of the marginal zone increases the cross figures become rarer and smaller the more delicate formations predominate and the background becomes more dense. The authors give photomicrographs of the normal fluid and also of several pathologic specimens.

Antimony Derivative in Treatment of Syphilis—Kritschewski and his associates relate their studies on the antisyphilitic action of antimony preparation in animals and human subjects. They found that the preparation destroyed the spirochetes not only in rabbits but also in mice and in human beings. The preparation sterilized the central nervous system of syphilitic mice. In human subjects the antisyphilitic action of the

antimony preparation was not inferior but rather superior to that of bismuth compounds. The authors conclude that antimony preparations deserve a place in the combination therapy of human syphilis.

Sodium Chloride Exchange in Amyloid Kidney—Nonnenbruch noted in healthy persons that a dry diet with high sodium chloride content is one of the strongest diuretics. He decided to try this diet on patients with hydropic nephrosis or with amyloid kidneys in order to discover whether the sodium chloride would exert its diuretic action and produce an increase in the sodium chloride content of the urine. In one patient, in whom the specific gravity of the scant urine did not exceed 1.020, the sodium chloride values of the urine remained below the blood values and there was hardly any diuresis. In another case, however, diuresis and sodium chloride concentration resulted. This patient had a chronic suppurative pulmonary process, bronchiectasis, empyema and amyloidosis. Death occurred eight months later and the necropsy revealed the presence of amyloid in the internal organs. The author wished to illustrate in this case that even in case of edema with oliguria and with low sodium chloride concentration of the urine in the course of an amyloid nephrosis it is possible to produce the strong diuretic action of the sodium chloride with simultaneously decreased fluid intake, provided the kidney is capable of reacting to the sodium chloride. If hyponatremia exists, the administration of sodium chloride is advisable even though renal disease is present. This rule is followed in case of poisoning with corrosive mercuric chloride and also in true uremias in chronic renal diseases. In these cases the vomiting is often promptly checked by the intravenous administration of sodium chloride.

Magnesium Chloride Test: Reaction for Serum Proteins—Bauer describes a test for the determination of the protein quotient in the serum, which is based on the investigations of Pauli, Neuberg and Willheim who proved that heat flocculation of protein solutions can be prevented by the addition of saturated solutions of hydrotropic salts. After many preliminary tests the author found that the use of an exactly one third saturated solution of magnesium chloride (15.68 per cent), which is prepared by titration with silver solution, is the most suitable for this purpose. A dilution series of serum and physiologic solution of sodium chloride is set up in six tubes, the first containing 1 cc. of a 1:2 serum solution. To the 1 cc. of serum solution in each tube, 1 cc. of the solution of magnesium chloride is added. The tubes are heated for fifteen minutes in the boiling water bath. Under normal conditions, flocculation takes place only in the first two tubes, but if the globulin is increased, it takes place also in the third and the following tubes. As a rule, flocculation is noted only if the globulin content exceeds 40 per cent but, if the euglobulin factor predominates, flocculation may set in when the total globulin amounts to only 30 per cent. The author made tests on 652 serums and his observations convinced him that the test is always negative in normal persons and also in the majority of patients. The eighty-five persons (13 per cent) in whom the test was positive had various disorders, some having hepatic diseases and others pernicious anemia. The third group in whom it was positive, had tuberculosis, but only seventeen of sixty-nine gave the positive reaction. Of thirty-five patients with a positive Wassermann reaction, twenty-five gave a negative magnesium chloride test. Patients with carcinoma also

gave mostly negative reactions, but out of twenty-four were strongly positive and two weakly positive. The sixth group in which the test was found positive embraced patients with diverse disorders, such as poisoning with barbitals, hernia, tonsillar abscess, facial paresis and pneumonia; positive results were seen also after milk injection, after injections of tetanus serum and during malaria therapy. The author thinks that in diseases of the liver and in pernicious anemia the test has a certain diagnostic value.

Coagulation Test in Diagnosis of Hepatic Diseases—Weltmann and Sieder made the coagulation test on patients with liver disease. The width of the so-called band is expressed in the number of tubes that show coagulation. Since in the series of ten tubes the critical zone often lies between the seventh and eighth tube, and additional tube is intercalated here (7½). On the basis of observations in hepatic disorders the authors conclude that the coagulation test is helpful in the diagnosis of liver diseases. The behavior of the coagulation band in simple icterus and in acute yellow atrophy of the liver indicates that parenchymal damage of the liver produces changes in the serum protein. The extreme width of the coagulation band in acute yellow atrophy of the liver, which exceeds that of simple icterus, indicates that the width of the coagulation band is largely determined by the intensity of the impairment of the liver cells. In cirrhoses of the liver a widening of the band is likewise an almost constant occurrence. However, in these cases a connection between the greater width of the band and the degree of parenchymal damage is not so unequivocal since here a second factor is involved, namely, the fibrous tendency. In this connection, the authors call attention to their experiences with the coagulation test in tuberculosis, in which they found that the coagulation band was narrowed in the exudative forms while it was widened in fibrous processes. The primary parenchymal diseases of the liver are the ones in which the coagulation band is particularly valuable. In these the coagulation reaction is more sensitive than the galactose test but somewhat less sensitive than urobilinuria. A disadvantage of the coagulation test lies in the fact that the nongenuine secondary alterations of the parenchyma, such as may be observed after prolonged biliary engorgement and in extensive destruction of the liver tissue by carcinoma, may also lead to a widening of the band. The identical outcome of the galactose and of the coagulation tests, whether positive or negative, is an unequivocal indication of the presence or absence of parenchymal impairment. However, a divergence between the two, negative galactose test and wider coagulation band, may be interpreted in various ways. It is possible that parenchymal impairment exists, in which the galactose test fails, or there may be a biliary stasis that secondarily leads to functional damage of the liver. A positive galactose test with no widening of the galactose band is rare, but if it occurs it indicates an impairment of the liver cells accompanied by an exudative inflammatory process.

Blood Pressure in Upper and Lower Extremities—Edelmänn and Kahan point out that Hill first studied the causes of the difference in the blood pressure between the upper and lower extremities in aortic insufficiency. Even in normal persons, differences in pressure exist between the arms and legs, the systolic pressure in the latter exceeding that in the arms by from 10 to 14 mm. of mercury. However, in aortic insufficiency, Hill found differences of from 50 to 100 mm. of mercury. Several other investigators have corroborated Hill's

observations, but there is still disagreement as to the causes of this phenomenon. The authors show that the stenosis of the aortic isthmus throws light on the mechanism of the pressure difference. They show that the difference between the blood pressure in the upper and lower extremities is dependent on the obstacles that the blood stream encounters on its way. Of especial significance is the right-angled branching off of the artery of the arm. Moreover, syphilitic changes of the aorta causing distortion and stenosis at the site where the artery of the arm branches off, lead to differences in the blood pressure by increasing the resistance. Hill's symptom has practical significance in that it indicates a syphilitic lesion at the beginning portion of the aorta, but arteriosclerotic changes of the smaller vessels, such as the subclavian, brachial femoral and popliteal arteries, which cause a narrowing of the lumens, likewise may lead to differences in the pressure.

Acute Cardiac Pulmonary Edema and Its Reflex Mechanism—Wassermann shows that acute cardiac pulmonary edema presents in certain cases a reflex syndrome of the cardiac pulmonary sympathetic nervous system with radiations into other regions. It can be improved or entirely suppressed by pressure on the carotid sinus. The attack of pulmonary edema generally occurs spontaneously with cardiac acceleration, increase of the blood pressure and symptoms of irritation of the sympathetic. The objective symptoms are dyspnea, moist rales and serohemorrhagic sputum. The author thinks that the condition is produced by a cardiac central pulmonary reflex in the region of the pulmonary capillaries (spasm) with exudation of serum into the alveoli. At the height of the attack there is danger of primary respiratory death or of secondary heart failure. Pressure on the carotid sinus presents a complex counter reflex. The spontaneous attack of pulmonary edema is not an exclusive nocturnal phenomenon but occurs almost as frequently diurnally. Frequent diurnal attacks of asthma should be carefully investigated in order to determine whether they are not atypical forms of pulmonary edema. During the attack the following measures may be taken: compression of the carotid sinus, quieting of the central apparatus of the respiration and deviation of the reflex by hot hand and foot baths or hot fomentations on the precordial region and by administration of spasmolytic remedies. Helpful supplementary measures are oxygen inhalation, venesection and in case of cardiac insufficiency, digitalis. If the asphyxia increases, restoratives may be given or remedies that stimulate the respiratory center. During the interval, the irritability should be reduced by the use of sedatives. The water exchange should be regulated by limiting the fluid intake. The cardiac insufficiency and the coronary circulation should be improved by chronic intermittent digitalization. This would reduce the coronary irritability, effect a better blood perfusion of the nervous centers and thereby reduce the predisposition to attacks.

The Trichomonas Problem—Rodecurt evaluates the various staining methods of trichomonads. The demonstration by means of stains is not superior to the fresh preparation. For practical purposes the fresh preparation is the best. The author describes his experiences with trichomonas cultures. He produced pure cultures of trichomonads and observed that they survived several freezing processes and drying. He succeeded in producing trichomonas vaginitis by introducing the trichomonads from a pure culture. He discusses the biology of trichomonads. Eighty-eight per cent of his leukorrhea cases

were caused by trichomonads. He evaluates various therapeutic measures and shows that besides the local ones those that aim at a general improvement (calcium, iron, viosterol and so on) should not be overlooked.

Cystic Mole and Chorio-Epithelioma—In 8,000 deliveries Winter observed twenty cases of cystic mole and three cases of chorio epithelioma. Expulsion of the mole always took place between the second and seventh month of pregnancy and retention was never observed. He states that the discharge of the characteristic cysts is the most reliable basis for the diagnosis of cystic mole, but this proof is relatively rare. Excessive size of the uterus is a further sign, but this is not always present. A peculiar consistency of the uterus, namely, a softness and yet a sort of tight elasticity that gives the impression of a cyst, is a characteristic aspect of cystic mole. Hemorrhages and the impossibility of demonstrating a fetus are also symptoms that may indicate a cystic mole. Some authors have observed toxicosis of pregnancy in women with cystic mole, but the author maintains that eclampsia as well as severe nephropathy are rare concomitants, although hyperemesis is somewhat more frequent. He considers the occurrence in the urine of an excessive amount of the hormone of the anterior hypophysis the most important symptom. Another sign he observed in nearly all cases is excessive mammary secretion. The treatment should aim at removal of the growth. Evacuation of the uterus is usually spontaneous but occasionally the discharge has to be assisted by the administration of echolics. However, after the cystic mole has been expelled the patient cannot be considered completely cured for now begins the prophylaxis of chorio epithelioma. The causal connection between cystic mole and chorio epithelioma is not completely understood, but chorio epithelioma is frequently preceded by a cystic mole and both disorders are accompanied by hormonal disturbances. Of the three cases of chorio-epithelioma observed by the author, one developed following a cystic mole and two developed after delivery. He emphasizes that if hemorrhages develop shortly after a delivery not only the possibility of a placental polyp should be considered but also the existence of a chorio-epithelioma. Women who have had a cystic mole should be kept under observation, that is, the urine should be examined from time to time for its hormone content. If the hormone test remains positive for longer periods, the woman should be examined.

Gas Gangrene Bacilli in Vaginal Secretion—Von Khreninger-Guggenberger examined the vaginal secretions of twenty pregnant women, two puerperal women and seventy-five nonpregnant women. By means of cotton swabs he secures secretion from the posterior vaginal vault. The swabs are placed in a liver-liver broth (liver broth containing pieces of the organ). In this medium the gas gangrene bacilli develop faster than any other gas formation being noticeable after a few hours. As soon as gas formation is noted the fluid culture is transferred to Zeissler's blood plates. These blood plates are then placed in the incubator for anaerobes. Then, in order to determine the pathogenicity for animals a twenty-four hour bouillon culture is prepared from the pure culture and 0.5 cc of this is injected into the pectoral muscle of guinea pigs. If the reaction is positive a typical gas gangrene phlegmon appears and most of the animals die within twenty-four hours, while others survive but show necrosis formation. The tests revealed that in approximately one third of the pregnant women the upper portion of the vagina contained gas gangrene bacilli. One of the two puerperal women and eight of the seventy-five nonpregnant women had gas gangrene bacilli in the vaginal secretion. The author shows that the pathogenic microorganisms of the vagina are kept in check by the vaginal secretion but a dilution of this secretion removes the growth.

inhibiting power. He maintains that the growth-inhibiting power of the vaginal secretion decreases as the duration of the delivery is prolonged and, if delivery lasts too long, sepsis sets in. For this reason he advises that prolonged birth should be accelerated by the administration of hormones, or, if complications may be expected, operative measures should be taken early enough, for the earlier the intervention, the better the results.

Liver Function Determination in Prevention of Neorarsphenamine Complications.—Markus and Gelfand consider that the more functional the tests the more accurate will be the determination of the liver function as regards not only the icterus but also the complications due to neorarsphenamine in a broader sense. The following factors play an important part in the pathogenesis of secondary effects of neorarsphenamine, particularly of icterus after neorarsphenamine: 1. Latent infections (streptococci, paratyphoid, *Bacillus subtilis* and so on). Here the neorarsphenamine because of its hepatotropic effect, can activate the bacteria by lowering the functional status of the liver. 2. Dietetic errors, in the form of insufficient carbohydrate content. To reduce the incidence of these complications, the authors recommend that the following measures be carried out before and during the course of the mixed treatment: 1. Careful anamnesis and observation of the patient should be done, with particular attention to the general state, rises in temperature, attacks of malaise, headaches and rheumatic pains. 2. Proper evaluation should be given to even the mildest gastro-intestinal disturbances in the present and the past. 3. The importance of the diet should be emphasized, with elimination of alcohol and seasoned foods, and a sufficient amount of carbohydrates. 4. In addition to the investigation of the cardiovascular and the nervous system, and urinalysis, it is obligatory to examine the liver in all syphilitic patients by palpation and percussion paying attention to pain below the ribs, a sense of weight in the epigastrium, icteric and subicteric manifestations, itching, bradycardia and enlargement of the liver and the spleen. 5. Infectious processes both in the present and in the past must be carefully estimated. 6. Strict adherence should be observed to established dosage and intervals in the administration of neorarsphenamine. 7. The functional state of the liver should be estimated, based on several tests, some of which, such as the icterus index and the urobilinogen reaction, may be carried out in ambulatory practice. The authors emphasize that positive tests indicating liver insufficiency do not exclude the specific mixed treatment but make it imperative to observe strictly the precautions mentioned and to repeat the study of the functional state of the liver.

Functional Capacity of the Stomach in Pulmonary Tuberculosis.—From a study of the gastric secretion in 124 patients with pulmonary tuberculosis, Moshkovskiy makes the following deductions: 1. Most of the patients with pulmonary tuberculosis display disturbances of the secretory function of the stomach. 2. Inactive and mild types of the disease generally show hyperacidity, while active and toxic types are inclined toward subacidity. 3. Strict parallelism between the toxicity of the process and the disturbance of the gastric secretion was not observed. The alterations in gastric secretion did not seem related to the subjective complaints of the patient. 4. In most cases, secretion reached its maximum during the second hour after the test meal. Nevertheless there is no reason to consider the delayed secretion as characteristic of a tuberculous intoxication. 5. Definite types of gastric secretion characteristic for tuberculosis could not be established either with the method of double stimulation of Zimnitskiy or with the fractional method of Katsch. 6. In 88 per cent of the total cases the empty stomach was found to contain gastric juice. Tuberculous toxemia has a depressing effect on the functional activity of the empty stomach. The more severe the tuberculous process,

the rarer the finding of free hydrochloric acid and the lower the general acidity. 7. Evacuation of contents was found to proceed normally after the test meal. 8. Lack of regularity is the most characteristic feature of the gastric secretion in tuberculosis. Repeated observations demonstrated that subacidity frequently alternated with normal amounts and even hyperacidity. 9. The frequent heterochylia proves that the depression of the secretory function is caused not by an organic insufficiency of the secretory mechanism but by a certain lack of stability of the vegetative system. 10. The alkali reserve of the blood was not found to depend on the acidity of the gastric juice.

*1. Roentgenologic Investigations on Development and Course of Juvenile Kyphosis. 2. Some Investigations on Vertebral Epiphyseal in Animals and Man. H. Scheuermann—p. 85

Roentgenologic Investigations of Juvenile Kyphosis.—Scheuermann's discussion of the pathogenesis and development of juvenile kyphosis is based on eighteen cases, in thirteen boys and five girls. Detailed report of the cases is given. Usually, he says, two or three vertebrae are affected, the most marked changes appearing in the body from the ninth to the eleventh dorsal vertebra. As a rule the changes coincide with the development of the vertebral limb, and a wedge shape of the vertebra results assumed to be caused by pressure into the spongy substance of the cartilaginous layer of the body, probably together with reduction in growth. The irregular vertebral contour is regarded as due to the irregularly developed border of the vertebra in connection with possible nucleus prolapse. Fixation of the kyphosis may occur in the course of half a year, and the wedge shape corresponds to the degree of kyphosis. Prognosis cannot be made at the start of the disturbance.

Pellagra. New Case. H. Boas—p. 153

Fixation of the Complement in Identity of Zoster and Chickenpox Virus.—Thomsen reviews the relation between zoster and chickenpox. The results were negative in his personal investigations on the fixation of the complement (analogous to those of Netter and Urbain) with application of serums from eighty-eight cases of zoster and extract of zoster and chickenpox crusts as antigen and of serums from fourteen cases of chickenpox and zoster antigen.

Cholesterol in Serum During Pregnancy.—Teilum says that pregnancy is accompanied by a hypercholesterolemia, often found in the third month and seldom absent later. He assumes that when the ovum has reached a certain stage of development (about the third or fourth month) a retention of cholesterol occurs in the mother, probably from the mother's organism (corpus luteum, reticulo-endothelial apparatus, suprarenals), and only to a slight degree from the food. Cholesterolemia has been considered necessary for the development of tissue in the fetus, but at least part of the fetal cholesterol may come from the placenta or endogenously from the suprarenals. Whether the mother's cholesterolemia is to be considered in connection with the cholesterol needs of the fetus is therefore doubtful. The cholesterol during pregnancy is believed to protect the mother's organism in different ways. Low cholesterol values in hyperemesis have been shown by other investigations.

CHRONIC NONSPECIFIC ARTHRITIS

ETIOLOGY AND TREATMENT, WITH SPECIAL REFERENCE TO VACCINE THERAPY

BENJAMIN H. ARCHER, M.D.
NEW YORK

In a recent communication dealing with the progress that has been made in the knowledge of chronic arthritis, Cecil¹ enumerates the following milestones

- 1 The recognition of the two great types of chronic non-specific arthritis
- 2 The theory of focal infection
- 3 The modern bacteriology and serology of arthritis
- 4 Investigations into carbohydrate metabolism and the more recent studies in vitamins
- 5 New methods in the application of physical therapy and climatology
- 6 Advances in the surgical and orthopedic treatment of chronic joint disorders

The object of this study is to evaluate some of these advances in the light of an experience during the past ten years with the care and investigation of more than 2,000 cases of chronic nonspecific arthritis²

CLASSIFICATION

The recognition by Garrod³ of the two great types of chronic nonspecific arthritis was a definite advance in the classification of the disease, truly as distinctive as the separation of gout from other joint disorders. To describe the two forms of the disease Garrod employed the terms rheumatoid arthritis and osteo-arthritis. The pathologic studies of Nichols and Richardson⁴ in a measure substantiated this division. These authors found that rheumatoid arthritis is primarily a proliferative and osteo-arthritis essentially a degenerative process. Allison and Ghormley⁵ have corroborated these observations and in addition have described a cellular disturbance in rheumatoid arthritis which they failed to encounter in osteo-arthritis. Cecil has stated that "these fundamental differences between rheumatoid arthritis and osteo-arthritis suggest that they are independent disease entities of different etiology and such indeed appears to be the case." Dawson, Sia and Boots⁶ are

in essential agreement with this point of view and emphasize the distinction between the infectious nature of rheumatoid arthritis and the noninfectious character of osteo-arthritis.

On the other hand, clinical experience has led many students of the subject to the conclusion that no such arbitrary division can be made. Too many cases show characteristics of both forms of the disease. There is definitely a mixed form of chronic arthritis. Combined types do occur frequently enough to upset any dogmatic classification. In a series of 1,459 cases of chronic arthritis reported two years ago, I⁷ found fifty instances in which rheumatoid arthritis and osteo-arthritis could be demonstrated in the same patient, frequently in the same finger. More recently Rigler and Wetherby⁸ in a roentgen study of sixty cases of chronic arthritis found that only 37 per cent showed a uniform type of pathologic change in all the joints. About two thirds of the patients had a mixed type of reaction in various joints. According to Kulowski,⁹ quoting Knaggs, the osteo-arthritic and the rheumatoid forms of chronic arthritis are opposite ends of the same scale of a single disease. Fisher¹⁰ declares that the two conditions may be present in the same patient but affecting different joints. McCrae¹¹ has stated that certain cases show features that seem to suggest distinct entities but others seem to belong to both groups or to lie between them. He feels that there are so many examples of these mixed cases that they offer a great objection to the adoption of the view that two diseases can be distinguished. He adds that in all chronic joint changes it is well to keep in mind that different results may come from the same cause and that the same result may be due to different causes. It is interesting to note that Nichols and Richardson,⁴ whose description of the pathologic changes of this disease is classic, held the same opinion regarding the causation of chronic arthritis. According to Dawson and Boots,¹² the changes initiated by infection may be followed by secondary degenerative alterations in such a way that the essential picture may closely resemble that of osteo-arthritis. Klinge and Fricke¹³ have given experimental proof of this contention. They have shown in rabbits that inflammatory arthritis becomes

degenerative arthritis if followed for a period of from one to three years Pemberton¹⁴ maintains that "whatever the criteria we accept the two great types of arthritis cannot definitely and finally be wholly divided one from the other. Allowing these two types their most specific features, they still in some part overlap and furthermore there is a group of cases which by common consent of students of arthritis throughout the world cannot surely be placed under either head."

An interesting suggestion is made by Richard and Joseph Kovacs¹⁵ that the type of nonspecific arthritis present in any given case depends on the anthropometric measurements of the patient, the rheumatoid form developing in persons of the asthenic type and osteo-arthritis coming on in individuals of the so-called pyknic or sthenic build. Boyd's¹⁶ conception of the disease is one of varying responses to a single cause. Rigler and Wetherby⁸ believe that the age of the patient, the joints involved and the duration of the disease are more important in determining the type of arthritis present in any given case than any causative factor or group of factors.

While it is true that in the early stages most cases of chronic nonspecific arthritis are either predominantly of the rheumatoid or predominantly of the osteo-arthritic type, as the disease progresses this distinction tends to become less marked. In the really mixed forms it is often impossible to say where the rheumatoid arthritis ends and the osteo-arthritis begins. In such cases the patient may present fusiform enlargement of the proximal phalangeal joints and Heberden's nodes of the terminal phalangeal joints. These are considered respectively, to be the characteristic clinical signs of rheumatoid arthritis and osteo-arthritis. To ascribe these lesions, which may be found in adjacent finger joints, to two different diseases requires a unique conception. It seems much more logical to assume that the synovial proliferation in the proximal phalangeal joints and the cartilaginous erosion in the terminal phalangeal joints are different manifestations of the same disease.

When one stops to consider the protean clinical and pathologic manifestations of other chronic diseases such as tuberculosis or syphilis, one is less apt to seek different etiologic agents to explain the synovial and cartilaginous changes in chronic nonspecific arthritis. It may be recalled in this connection that until the inflammatory lesion of the chancre and the degenerative cord lesions of tabes dorsalis were known to be due to a single etiologic agent, it was felt by most investigators that these were two different diseases with diverse etiologies.¹⁷ In the osseous system, it is well to remember that syphilis may manifest itself as a proliferative arthritis or as a degenerative process of the Charcot type. The pathologic changes of the proliferative form are quite similar to those of rheumatoid arthritis, and Boyd¹⁶ has pointed out the resemblance between the early degenerative lesions of the Charcot joint and osteo-arthritis.

There would thus appear to be a basis for the concept that both rheumatoid arthritis and osteo-arthritis are due to the same etiologic agent or group of agents and

that the proliferative and degenerative pathologic changes by which the two types manifest themselves are the result of other factors than those of causation. While age and the duration of the disease appear to be important factors, trauma, foci of infection, the involutional changes of the menopause, and the habitus of the patient seem to play a significant role in determining the type of nonspecific arthritis present in any given case.

BACTERIOLOGY

In the realm of bacteriology some interesting contributions have been made in recent years that in a measure corroborate the earlier work of Rosenow.¹⁸ In 1928, Forkner, Shands and Poston¹⁹ published their observations on the study of the synovial fluid in sixty-three cases of chronic arthritis. Positive cultures were obtained from the joint fluid in 22 per cent of the total number of cases. In 1929 Mary Poston,²⁰ one of the collaborators in this work, reported the results of taking cultures of 120 glands removed from patients with "chronic infectious" (rheumatoid) arthritis. Using Rosenow's technic, she obtained positive growths in 60 per cent of the cases. The predominant organism recovered in both investigations was a green streptococcus. In the same year Cecil, Nichols and Stainsby²¹ reported the isolation of an attenuated hemolytic streptococcus from the blood and joints of patients with rheumatoid arthritis. These authors studied seventy-eight cases and isolated a streptococcus from the blood in forty-eight instances. In forty of the positive cases they found a "typical strain" of streptococcus. Of the eight remaining strains, six were classified as viridans and two as indifferents. In addition to these organisms, they isolated diphtheroid bacilli in four cases and *Micrococcus zymogenes* on two occasions. A group of control cases, including nineteen instances of osteo-arthritis, gave negative results on blood culture. Cecil is disposed to pry but little attention to the isolation of any of the organisms but the streptococci and believes that the "typical strain" is the specific etiologic agent of rheumatoid arthritis. In their last series of 154 cases, Cecil, Nichols and Stainsby²² recovered streptococci from the blood in ninety-six cases (62.3 per cent) and from the joints in thirty-three of forty-nine cases (67.3 per cent). Since this work was originally published, streptococci have been isolated from the blood and joints of patients with chronic arthritis in a high percentage of the cases by Gray, Fendrick and Gowen,²³ Wetherby and Clawson,²⁴ Ashworth,²⁵ and Klugh.²⁶ Other observers²⁷ have found streptococci in the blood and joints of

arthritis patients but in a lower percentage of the cases (from 5 to 15)

On the other hand, a number of investigators have failed to corroborate the results of Cecil, Nichols and Stainsby Nye and Waxelbaum²⁸ in a very careful study found only one positive blood culture in a series of thirty-three rheumatic cases. They are inclined to regard the streptococci recovered from the blood and tissues of patients with rheumatoid arthritis as contaminants. These authors point out that the organisms now being found in arthritis cases are quite similar to those which were isolated twenty years ago from the lymph nodes of patients with Hodgkin's disease. Bernhardt and Hensch²⁹ found no streptococci in a series of twenty cases of rheumatoid arthritis in which eighty blood cultures were taken. Dawson, Olmstead and Boots³⁰ found only three positive streptococcus cultures in a series of eighty cases of rheumatoid arthritis, a little less than 3.7 per cent. It is noteworthy that these investigators isolated streptococci in two instances from the culture mediums, samples of sterile agar which were used as controls and were subjected to the same manipulations of the Cecil technic as were the blood cultures. Jordan³¹ failed to isolate any streptococci from the blood of thirty-two patients with acute forms of arthritis. He recovered some gram-negative and gram-positive bacilli but questioned their importance.

Numerous observers²⁷ have found streptococci in from 5 to 15 per cent of the blood cultures in arthritis cases. It must be emphasized in this connection that Lichtman and Gross,³² in a study of 5,233 consecutive blood cultures performed at the Mount Sinai Hospital in New York, reported a regular yearly incidence of from 5 to 15 per cent of cases positive for streptococcus in nonrheumatic diseases, such as pernicious anemia, leukemia, meningococcal meningitis and aplastic anemia. It follows, then, that the finding of this percentage of positive streptococcus blood cultures in rheumatic cases has no special significance.

The results of those investigators who reported a high percentage of positive blood and joint cultures in chronic arthritis show no uniformity. Cecil, Nichols and Stainsby²¹ have isolated an attenuated hemolytic streptococcus from the blood and tissues of rheumatoid cases but report negative results in their cases of osteoarthritis, used as controls. On the other hand, Wetherby and Clawson²⁴ report the isolation of indifferent and viridans strains of streptococci and find these organisms in the blood of osteo-arthritis as well as rheumatoid patients. Klugh²⁶ recovered a green streptococcus from the blood of arthritis patients and asserts that this organism bears a marked resemblance to the streptococcus which Small has isolated from cases of rheumatic fever. Ashworth²⁵ found gram-positive diplococci as well as streptococci in his blood cultures. The streptococci isolated by this author differ in their reaction toward the gram stain, only a few show hemolysis, most do not, and the fermentation reactions are irregular. Gray and his associates²³ have found viridans as well

as attenuated hemolytic streptococci in blood and joint cultures of rheumatoid cases. It is also of interest to note that Shands, who collaborated with Forkner and Poston in the cultivation of streptococci from the synovial fluid and glands of patients with rheumatoid arthritis, has later reported the finding of streptococci in two of ten Charcot joints and in one gonorrheal arthritis joint (with gonococci).³³

In view of the foregoing data it would appear that there is ample ground for skepticism regarding the actual presence of streptococci in the blood and joints of patients with chronic nonspecific arthritis. The probability of contamination must be borne in mind, because the colonies of the "typical strain" resemble very closely those which Olitzsky and Long³⁴ have isolated as contaminants in their work on the relationship of streptococci to encephalitis and poliomyelitis. These investigators found that the streptococci that were isolated were derived from ground meat particles. The colonies of these organisms had a greenish tinge and were surrounded by a narrow zone of hemolysis on blood agar plates corresponding very closely to the colonies of Cecil, Nichols and Stainsby's "typical strain." Long, Olitzsky and Stewart³⁵ have definitely shown that even under the most rigorous Carrel technic streptococci may appear in Petri dishes exposed to the air. Seven times as many colonies appeared under the usual conditions of sterility (under a hood) as were found under the more rigorous aseptic conditions of Dr. Carrel's tissue-culture room. These authors found a correlation between the number of positive cultures and the number of bacteria in the air. They further showed that these streptococci are introduced into the cultures during the process of grinding tissues. The streptococci were isolated from the air of the places where cultures were made.

VACCINE THERAPY

In recent years the treatment of arthritis patients with vaccines has attracted considerable attention and discussion. This form of therapy has been based for the most part on the assumption that the streptococcus is the etiologic factor in the production of chronic arthritis. It is principally used in the rheumatoid type of the disease but is also employed quite extensively in the treatment of osteo-arthritis.

Most observers report unsatisfactory results with this therapeutic agent. Pemberton states that when he needs a case suitable for vaccine therapy to demonstrate to his students he must search far and wide. He agrees with Kolmer that the results with vaccine therapy in chronic arthritis have not been encouraging and stresses the psychologic factor in the use of injections.³⁴ Osgood³⁶ has expressed his doubts of the value of this therapy. Kinsella³⁷ reports that the use of streptococcus vaccines in his experience has not been followed by encouraging improvement. Boots and Dawson¹⁷ state that it is their feeling that the results of vaccine therapy vary with the enthusiasm of the user.

Cecil¹ is noncommittal about his results with vaccine therapy and reports that at the present time he usually

tries intravenous injections of streptococcus vaccine for three or four months. If it fails to help, he discontinues this therapy. The "typical strain" of streptococcus vaccine is the one employed. In a recent communication, Stansby and Nichols³⁸ report that their results with this particular vaccine have been extremely disappointing. They feel that even "the low percentage of improvement in their series of cases may well represent the natural tendency of some patients to improve regardless of treatment, rather than any inherent value in streptococcus vaccine therapy." These authors report better results with other forms of streptococcus vaccine than with the use of the "typical strain." Furthermore, their patients do better with subcutaneous than with intravenous injections in contrast to Cecil's experience. Most difficult to explain is the fact that their moderately severe cases do better than their mild ones on this therapy. When one can improve relatively severe instances of a disease and fails to check mild cases with the same remedy, it tends to bespeak some other factor than the agent employed as the cause of the improvement. Nichols and Stansby apparently realize this and stress the importance of the psychologic effect on the patients of vaccine inoculations.

Personal experience with the "typical strain" vaccine at the Cornell Clinic and in private practice corroborates the results obtained by Stansby and Nichols. Whether this vaccine was given parenterally or intravenously in minute doses with the idea of desensitization, I have failed to observe satisfactory results. More recently, Wetherby and Clawson's vaccine³⁴ was tried intravenously. The acute cases were treated in the wards of Lincoln Hospital and the chronic cases were selected from private practice. I have failed to note any changes in the patients with the use of this vaccine. Prior to 1929, Cecil and I used vaccine of *Streptococcus hemolyticus* and *Streptococcus viridans* of autogenous and stock strains in a series of cases of rheumatoid arthritis. The effects were admittedly poor and were so reported.³⁹ Vaccines prepared from single organisms other than the streptococcus, such as *B. coli* isolated from the stool, or grouped with streptococci recovered from the nose and throat or other foci, also gave negative results in this type of arthritis.

In 1931 Burbank and Christensen⁴⁰ reported on the "specific vaccine therapy of 1,000 cases of chronic arthritis." The vaccine employed was the polyvalent mixed type consisting of autogenous and stock strains of streptococci, staphylococci, *B. coli* and at times gonococci. The authors assert that favorable results were obtained with this therapeutic agent, and its use is quite extensive at the present time. In their communication, Burbank and Christensen state that the basis for their method of treatment is the fact that "there is sufficient evidence of streptococcal culpability in all types to warrant considering both the atrophic (rheumatoid) and hypertrophic (osteo-arthritis) infective." The isolation of streptococci from the blood in fifteen of 145 cases (10 per cent) of chronic arthritis is cited⁴¹ as direct proof of this contention. As already noted, this

finding has no special significance, since it has been reported in nonrheumatic as well as rheumatic cases. Furthermore, it must be borne in mind that both types of nonspecific arthritis have been produced experimentally by aseptic processes, such as ligation of the blood supply to the patella⁴² or the intra-articular injection of horse serum.⁴³ It is difficult to reconcile such evidence with the view that all forms of arthritis are the result of streptococcal infection.

Neither this vaccine nor any other of the streptococcus or mixed vaccines used at the present time in the treatment of chronic nonspecific arthritis have been included in the last edition of New and Nonofficial Remedies (1933). It might be well at this point to emphasize the following statement of the Council on Pharmacy and Chemistry: "The employment of bacterial vaccines should be based either on the discovery of the causative micro-organism by careful bacteriologic examination of the patient under treatment or on well established clinical knowledge which has shown the disease present to be regularly due to the activity of a definite germ."⁴⁴

CARBOHYDRATE METABOLISM AND VITAMINS

Investigations into carbohydrate metabolism and studies on vitamins have been included as advances in the study of chronic arthritis. In 1920 Pemberton and Foster⁴⁵ reported a diminished sugar tolerance in most cases of "chronic infectious" (rheumatoid) arthritis. This work received corroboration from Fletcher⁴⁶ and served as a basis for a marked restriction of carbohydrate intake to sufferers from rheumatoid arthritis. A careful analytic study⁴⁷ was conducted at the Cornell Clinic in 1929 to check Pemberton's results. Two parallel series of cases of "chronic infectious" (rheumatoid) and "menopause" (osteo) arthritis were submitted to sugar tolerance tests. In the typical cases of rheumatoid arthritis no evidence of a diminished sugar tolerance was demonstrable. In the osteo-arthritis group it was found that 70 per cent showed a lowered tolerance for dextrose. However, most of the cases showing this lowered tolerance had associated conditions such as hypertension, obesity and endocrine disturbances. As it has been demonstrated repeatedly that either hypertension⁴⁸ or obesity⁴⁹ or endocrine disturbance⁵⁰ may cause a lowering of the sugar tolerance, it was concluded from these studies that it was impossible to say that the diminished sugar tolerance found in the cases of "menopause" osteo-arthritis was related to the chronic disease of the joints.

I had discontinued the use of a low carbohydrate diet in badly nourished patients with rheumatoid arthritis

even prior to investigating carbohydrate metabolism, because it had become manifest clinically that these patients became definitely worse on reduction of their caloric intake. However, following the investigations of Fletcher⁵¹ and his advocacy of a vegetable diet plus a liberal supply of vitamins, I returned to this regimen for a time. In his studies on the colon in arthritis, Fletcher found a high percentage of abnormalities. He further reported that with the use of a "green" diet and a liberal supply of vitamins this pathologic condition could be corrected and the arthritis improved.

To check these results, a series of patients with rheumatoid arthritis were given barium enemas at the arthritis clinic of the Mount Sinai Hospital. It was found that many of the roentgenograms showed reduplication of the colon and incompetence of the ileocecal valve. However, inquiry from the gastro-enterologists at the hospital drew from them the reply that any parallel series of nonrheumatic cases would show the same percentage of colonic abnormalities which had been obtained in the arthritic cases, and that it was futile on the basis of such evidence to postulate any specific relationship between the changes in the colon and the disease under consideration. Recently Haft⁵² has published his results regarding colon changes in a series of rheumatic and nonrheumatic cases. He found the same high incidence of reduplications, ileocecal valve incompetence and lack of haustral markings in his control group as he did in his group of arthritis cases. He concludes that the expression of the abnormalities in the colon in the arthritis cases as well as in the control cases is a manifestation of chronic disease states rather than a condition that is peculiar to chronic arthritis. Clinically, the use of vitamins of all kinds, singly and in combination as also the use of any special dietary, has completely failed in my experience to exercise any specific effect on the joint manifestations of patients with nonspecific arthritis. It seems important to add that those patients who are poorly nourished should receive a well balanced, high calory diet to increase their general resistance. On the other hand, in robust individuals with painful weight bearing joints, a reduction in weight is often beneficial for purely mechanical reasons.

FOCAL INFECTION

The theory of focal infection still holds an important place in any consideration of chronic arthritis. With the years has come a more accurate appraisal of its undoubted benefits and its equally definite limitations. On the positive side it has been shown that in the mild forms of rheumatoid arthritis, in the early stages, removal of foci, especially diseased tonsils, will in a high percentage of the cases produce a prompt remission and in a smaller number, lasting recovery. In this connection it seems well to recall the frequency of remissions in this disease and to emphasize the fact that no case of arthritis can be considered as cured by any procedure unless followed up for at least two or three years, possibly longer. On such a basis the early mild cases represent the only form of rheumatoid arthritis that I have seen cured, and it was effected by the application of the theory of focal infection within six months of the onset of the disease.

Whether these mild cases of "periarticular arthritis" should be placed in the same category with the relentless form of "primary progressive polyarthritis" that goes on inexorably to bony ankylosis, in spite of the removal of foci, is a question that might very well form the basis of a separate report. It may suffice to state at this time that some observers⁵³ believe that the mild form of "periarticular arthritis," which is so frequently improved or cured by the removal of foci of infection, is not the same entity as "primary progressive polyarthritis." On the other hand, some keen students⁵⁴ of the subject believe the mild type to be the "anlage" of the malignant form of the disease and that the two differ only in duration, extent and severity. Since it is impossible to forecast whether an incipient case of rheumatoid arthritis is going to be benign or malignant in its later manifestations, it seems wise to search for and promptly remove diseased foci early in the course of the disease.

It should be emphasized that the tonsils are not the only possible source of infection. Abscessed teeth and severe pyorrhea come next in the order of frequency. More rarely the prostate, the colon, the sinuses, the gall-bladder and the cervix may act as a focus of infection in any given case. It has been my experience that extraction of teeth and treatment directed toward the less common foci do not produce the dramatic results of tonsillectomy. However, this is not intended to disparage the value of such procedures when indicated.

TREATMENT OF ADVANCED CASES

Rheumatoid arthritis in its fully developed and advanced form seems to be an incurable disease. Neither diet, nor vaccine, nor the removal of foci will cure this condition. As McLester⁵⁵ aptly puts it, there is only one thing left to do, and that is to treat the patient and not the disease. Kinsella⁵⁷ is of the same opinion, and Bauer⁵⁶ states that there is no specific therapy for rheumatoid arthritis and that every one treating these patients should study them carefully, correct all abnormalities, treat the patient as a whole and observe the effect on the course of the disease. This seems to be the consensus of the American Committee for the Control of Rheumatism, as voiced by Pemberton⁵⁸ on numerous occasions.

If this is true, what should be done to treat the patient with an advanced case of rheumatoid arthritis? Kinsella⁵⁷ advises that some "reasonable" measures be used. In my opinion these measures are (1) the use of orthopedic procedures, first to combat and secondly to overcome joint deformities, (2) the application of physical therapy, in its approved and accepted forms, (3) the administration of drugs to relieve pain, and (4) a climatic change from the humid and cold north to the warm and dry south.

A pitfall one should avoid in the present-day treatment of rheumatoid arthritis would seem to be undue concentration on one particular form of therapy. If the physician focuses his attention on a "fad" he may forget to treat the patient along more sound and more logical lines. Securing favorable results in a few cases, he may attribute specificity to a particular remedy and is apt to minimize his failures. The absence of a specific

⁵⁶ Pemberton Ralph. Arthritis. *Am J M Sc* 178 593 (Nov) 1929.

remedial agent seems to promote this tendency to overestimate the importance of some favored form of treatment. This in turn may lead to the exclusion of other well tried and valuable procedures. It would be well to bear in mind that in the present state of knowledge dogmatic views on therapy (as well as etiology) are not warranted by the facts. It seems to me that, pending further investigation, a broad point of view and an open minded attitude are essential for progress both in the study and in the treatment of patients with rheumatoid arthritis.

TREATMENT OF OSTEO-ARTHRITIS

It was formerly my custom to make a sharp distinction between rheumatoid arthritis and osteo-arthritis and to treat the former as an infectious and the latter as a noninfectious process. I have come to realize that this practice proceeds too much from an "a priori conviction as to what should be the case" and is based on limited premises. At the present time I examine and treat each case of arthritis solely on its own individual merits without necessary regard to its classification. Present knowledge of the subject does not seem to warrant the view that certain measures should be applied to certain types, since "there is no unequivocal evidence that the same measures do not apply to both types or that they always apply to either type." In the words of Pemberton,¹¹ "the time may come, and it is to be greatly hoped that it may, when the various forms of treatment can cluster with sharp definition around the two or more types of arthritis which may finally and permanently emerge. Until this time has arrived we should make ourselves familiar with the general principles and measures which may and often do apply to all types."

SUMMARY

1 There appears to be a basis for the concept that both rheumatoid arthritis and osteo-arthritis are due to the same etiologic agent or group of agents and that the proliferative and degenerative pathologic changes by which the two types manifest themselves are the result of other factors than those of erosion.

2 There seems to be no conclusive evidence of the presence of streptococci in the blood and joints of patients with chronic arthritis.

3 None of the vaccines employed at the present time in the treatment of chronic arthritis have been accepted by the Council on Pharmacy and Chemistry. There is no evidence at hand that they exercise any specific effect on the course of the disease.

4 Dietary regulations and vitamin therapy apparently exercise no specific effect on the joint manifestations of patients with this disease.

5 In those cases associated with foci of infection it seems wise to search for and remove this factor early in the course of the disease.

6 In advanced cases the measures I have found to be of greatest benefit to the patient are orthopedic procedures, physical therapy, the administration of drugs to allay pain, and a change of climate.

7 Present knowledge of the subject does not seem to warrant the view that certain definite measures should be applied only to certain definite types of arthritis. There is no conclusive evidence that the same measures do not apply at some time to all forms of nonspecific arthritis.

1964 Grand Concourse

VERIFIED BRAIN TUMORS

END RESULTS OF ONE HUNDRED AND FORTY NINE CASES EIGHT YEARS AFTER OPERATION

WILLIAM P. VAN WAGENEN, MD
ROCHESTER, N. Y.

In Dr Cushing's recent monograph on intracranial tumors a statement appears to the effect that what is more important than the mere statistical enumeration of the dead and the living is to know what has happened to the survivors. Toward this end, the present inquiry was undertaken.

During the summer of 1932 an opportunity presented itself to be associated again for a few weeks with the surgical service of the Peter Bent Brigham Hospital. With it came the privilege of reporting on the follow up of a group of Dr Cushing's patients seen during my term as resident in the neurologic service, now some eight years ago. The group selected for study comprised the "verified" tumors of the brain, 149 in number.

Scarcely is a person admitted to the hospital with a diagnosis of a brain tumor than one is beset with a whole train of queries by the family physician and the patient's relatives. Will he be able to return to work or former mode of living, and for how long? Will he be handicapped, will the tumor recur if removed, what is the probable length of life? All too hard pressed is one to answer these questions, and naturally some of them cannot be answered. The question most often asked is that of the patient's ability to return to work.

Every privilege naturally implies a responsibility, and in this instance the responsibility of making this report is a many sided one. The relatively small number of cases must be taken into consideration and too sweeping conclusions must not be drawn from them. A larger series would undoubtedly be of greater value and probably more accurate. The fact that the period of "useful activity" of this group, operated on now some eight years ago, may not represent end results possible today, must be borne in mind. Neurosurgical technique has improved in the last eight years. The electrosurgical devices now so commonplace were in their beginning at that time. The use of ether anesthesia was commonplace at the time these patients were operated on. Now it is rare. The fresh tissue diagnosis of tumors was almost unknown at that time and the gliomas were just being classified. The extent of operative procedures and of roentgen treatment is now guided considerably by such information. Diagnosis and localization are also more accurate than formerly, owing to the better understanding and greater use of ventriculography. Should each succeeding resident in this neurosurgical service tell a similar follow-up story of the people he saw during his year, each undoubtedly would have a still better account to render. This may be shown by one thing alone, namely, that the primary mortality has been reduced in the intervening eight years from 14.5 per cent to 6.8 per cent—a truly remarkable figure. Then too, the intangible nature of the data on which an opinion of "useful activity" is based must be taken into consideration. The follow-up reports on these patients have been remarkably good. Only one of the 149 patients has been lost track of entirely. The others have been reported on at least seven years after operation.

and most of them eight years. The information on deceased patients is 100 per cent complete. The period of survival and useful living is calculated from the date of the first operation. If, for example, a patient was operated on first in 1920 and was admitted for reoperation in 1924, the period of survival or useful living would date from 1920.

The term "economic worth" or "useful activity" must have some definition, even though it may not be a sharp one. What I or any one else, as a casual observer, might term a period of useless and unfruitful existence might be differently evaluated by the patient, particularly if he has gained freedom from violent bouts of headache, vomiting, the threat of oncoming blindness and convulsive seizures. Such relief of symptoms is an item that can never be quantitated or charted. There comes to mind the instance of a bright young reporter on the staff of one of the country's leading newspapers who had been irreparably incapacitated by an acoustic neuroma. His follow-up letters, however, are nothing but a flow of gratitude for the relief from headaches, vomiting and the threat of oncoming blindness. In any such report as this his eight year period of life must be listed as void of "useful activity" though to him it has not been so. However, as a working basis the ability to return, in a major part, to former duties or mode of living or educational projects has been taken as useful activity.

During the past twenty-five years or more a small group of men by an enormous amount of energy and labor have shown their confreres the value of neurosurgical measures in prolonging life. Whether it is incumbent on a younger surgeon, even though urged, to attempt to pass judgment on the worthwhileness of such a prolongation of life is indeed a very real question. Obviously the responsibility of such a report as this is to do justice not only to the person who has taken all the responsibility of the care of these persons but also to the general practitioner of medicine who honestly asks what his patient may expect and how the results of intracranial surgery compare with those of the surgery of tumors of the stomach, rectum, esophagus, breast, thyroid, long bones, and the like.

The 149 verified tumors are classified in table 1.

TABLE 1—Classification of Verified Tumors

Gliomas	80
Pituitary adenomas	26
Meningiomas cerebral	16
Acoustic neuromas	11
Congenital cysts	6
Metastatic carcinomas	4
Blood vessel tumors	4
Pinealomas	1
Heterotopia of cerebellum	1
	149

TYPES OF TUMORS

Gliomas—As a result of the work of Bailey, Cushing and others, this group of tumors is no longer one great undifferentiated mass, to either the pathologist, the surgeon or the radiologist. As they have pointed out since my year in the neurologic service, the life history and prognosis of the various groups of gliomas vary greatly. Some are practically benign and some are as rapidly growing as malignant tumors elsewhere in the body. The more primitive the cell structure, the more rapid the growth and spread seems to be. They have also pointed out favorite sites for the occurrence of certain

tumors, such for example as the medulloblastomas in the midline of the cerebellum. There were in this list of 149 verified tumors 80 gliomas which have subsequently been classified (table 2).

Much to my surprise, the best showing of any group in this entire list of tumors is made not by some of the so-called benign encapsulated tumors but by a group of gliomas, the cerebellar astrocytomas.

Of the eighty patients listed under gliomas, sixteen are now living and sixty-four are dead. The average

length of life of the group is 38.8 months. The estimated period of usefulness is 24.4 months. However, one needs to look further to comprehend this figure better, and each subgroup will be considered separately.

Glioblastomas and Medulloblastomas—What are now proved to be glioblastomas and medulloblastomas may be grouped together as a most unfavorable lot. The former are invariably cerebral tumors of brief history and rapid growth occurring in people of middle life. Fulminating symptoms of headache, vomiting and palsies were the rule. Extensive extirpations were usually followed by prompt recurrence. Roentgen therapy seemed to change the course of the disease little, if any. While operative procedures failed to allow any of the patients to return to work, it did afford many of them an enormous amount of comfort. A number were prominent business people who were able to put their affairs in order and, for the first time in years, really spend a few weeks with their families. What amounted to practically a demand for secondary operations because of the relief afforded by an original operation occurred in several instances. The length of life of twenty-one patients with glioblastomas averaged twelve months from the date of operation. All are now dead. None actually returned to work and only one to any semblance of the former mode of living.

The medulloblastomas, seventeen in number, were all, as usual, midline cerebellar tumors. They were practically all in young subjects. The survival period was 14.5 months. "Livableness" was estimated at about six months and consisted largely in the ability to return to school work. All members of this group are now dead. Nowhere, however, is the relief of symptoms more sought or more appreciated. Like the glioblastomas there is often a fulminating onset, severe bouts of headache and vomiting, and a rapid onset of disability. Decompressive measures, extirpation and roentgen treatment relieve these symptoms temporarily and allow the patients to live out the six and twelve month period of life in relative comfort. In a few instances a good survival period of from two to five years is recorded. Recurrence both locally and in the subarachnoid bed of the spinal cord and over the base of the cerebrum is the rule in spite of roentgen therapy and wide excision.

These two groups of tumors, in particular, most urgently need some adjunct to the treatment by excision and radiation

Cerebellar Astrocytomas—These cases, eleven in number, are a most hopeful group. When one considers both the total length of life after a first operation and the ability to return to former usefulness, they represent the best of all groups in the entire series. These tumors are relatively benign and if widely extirpated do not tend to recur with any great frequency. They are slow growing, tend to become cystic, and are usually found in the midline of the cerebellum or near it. The average length of life from the date of operation in the year 1924-1925 was ninety-one months. The average period of useful living was estimated at eighty months. However, if the survival period of all these patients is calculated from the date of the original operation, the average survival is 108 months, and the average useful living period is 97.2 months. M. F., for example, was first operated on in 1907 and again in 1924. He was reported well in 1933 and the total survival period is 300 months. Eight of the eleven in this group are still living. Had the principle of excision of mural nodules of these cystic tumors been in constant practice from the start, i. e., 1905-1906 the period of life as well as of useful activity would be still greater. One interesting fact stands out in considering the types of tumor associated with blindness. Practically all instances of it were associated with the cerebellar astrocytomas and the acoustic neurinomas. The slow growth and slowly developing hydrocephalus probably account for such a coincidence.

Oligodendrogliomas—Another more favorable group is that consisting of the oligodendrogliomas. There were four such tumors—all cerebral and all frontal lobe with a life span of seventy-four months and a livable period of fifty-four months. None of the patients, however, are alive at the present time.

Cerebral Astrocytomas—The cerebral astrocytomas, both fibrillary and protoplasmic, are far less favorable in the field of this survey than the cerebellar because of the accompanying palsies and the surgeon's hesitancy to do wide extirpations, which lead to palsies not already present. The percentage of such cerebral tumors, which become cystic and have mural nodules, is less than in the cerebellum. The five patients with fibrillary cerebral astrocytomas lived twenty-five months following operation, with a "well period" of twelve months. The eight patients with protoplasmic astrocytomas lived 32.5 months, with a "well period" of twelve months. None of this group have survived the eight years.

Astroblastomas—There were three patients with cerebral astroblastomas. Their survival period averaged twenty-four months. The useful period averaged twelve months. None are now living.

Ependymomas—Three ependymal tumors, all cerebral, proved to be a favorable group with a life span of seventy-eight months. Two of the three are now living and about their duties, although one has an occasional epileptic seizure. The third lived four and one-half years. The useful period for the group averaged fifty-four months.

Optic Chiasmal Glioma—One patient suffering from a glioma of the optic chiasm on last report was alive eight years after operation and has taught school for seven years.

Ganglioneuroma—One patient in this group lived thirty-six months, during which time he had about twelve months of ability to carry on his business.

Pinealomas—One example of this tumor was seen. A boy aged 7 years entered with an extreme hydrocephalus. Death occurred following an operation for its removal.

Miscellaneous—One patient with a tumor apparently arising from the lateral aspect of the medulla is still living and able to be about a good share of the time. The type of tumor is uncertain. The period of useful activity is estimated at about twenty-four months. Five cerebral tumors verified by cyst fluid only were probably astrocytomas from which the mural nodule was not identified and removed. The patients in this group lived thirty-seven months, with a period of useful activity of 9.4 months. None are now living (11, table 3).

The Encapsulated Tumors of the Nervous System—These tumors are made up of the pituitary adenomas, the congenital suprasellar cysts, the meningiomas and

TABLE 3—The Period of Survival and the Period of 'Useful Living' of 149 Patients with Brain Tumor Eight Years After Operation

Disease	Period of Useful Living Months	Average Survival Period Months	Number of Cases of Each Type

Total cases			149

the acoustic neurinomas. In any large series of cerebral tumors they constitute about 50 per cent of the whole.

The Pituitary Adenomas—This type represents a particularly favorable group. As a rule, patients with pituitary adenomas do not suffer gross palsies and, if a working degree of vision can be preserved, a return to their former mode of living is assured. A few patients suffering from pituitary adenomas with acromegaly are incapacitated from concomitant heart disease, diabetes, arthritis or generalized weakness. The period of useful activity for the twenty-six patients comprising this group is estimated at 76.4 months. The average length of life is eighty-seven months.

Twenty-two of the twenty-six patients are known to be living. Three have died. One death occurred a few hours after operation. A second patient died some twelve months after and a third some thirty months after operation. The fourth could never be traced and is counted as having a zero survival and "useful living" period.

Congenital Cysts—I feel certain that the suprasellar or congenital cysts observed, six in number, do not represent the average of a large series. One patient of the group proved to have a carcinoma of the wall of

a cyst, which had spread to the temporal lobe and the region of the gasserian ganglion. This patient lived eight months after operation. The period of livability was nil. A second and third were of unusual age for this malady to manifest itself, one being 62 and the other 59. The former was transferred from a psychopathic hospital for treatment. Even though the suprasellar cyst was adequately dealt with, the mental state of the patient was unaffected. The other person died following operation, of a thrombosis of a lateral and longitudinal sinus. The fourth, a man aged 21, had a few months of relief from headache, vomiting and incontinence after partial removal of a solid portion of a cyst wall. He then died following a secondary operation for removal of further extensions of the growth. The fifth is a brilliant result in the case of a 10 year old boy who is now alive eight years after operation. Aside from the preoperative loss of vision of one eye, he is well. The sixth had a period of useful activity for some eighteen months. The average period of useful activity of this group is twelve months. The average survival period is seventeen months.

Cerebral Meningiomas—These are divided into two groups: those associated with the convexity of the cerebrum and those found in the suprasellar region. The former will be considered first. Of the twelve patients with cerebral meningiomas, five are still living. Of the five now living, four consider themselves "well" and carry on their usual duties. One is incapacitated by a hemiplegia that was present before operation and did not clear up following the removal of the growth.

Seven of those having cerebral meningiomas have died. Four deaths occurred following removal of recurrent growths. Three others died at home. Their period of activity averages fifteen months of the thirty-seven months life span.

An average of this group, both living and dead, shows a period of useful activity of fifty months and an average life span of seventy-four months.

All told, the meningiomas probably represent one of the most difficult of all tumors to deal with surgically. To be able to add fifty months to the useful life of a person past middle age who is suffering from a neoplasm in any part of the body is an accomplishment of no small magnitude. Especially is this so when lack of intervention would mean either a continuance of an existing total disability or the early onset of one.

Suprasellar Meningiomas—The suprasellar meningiomas are four in number. Three of the four patients are still living. Three were about their usual duties. One patient, who was nearly blind on admission has not had any return of vision but is otherwise "well". The average period of usefulness is sixty-two and a half months. The average life span is eighty-four months. If cerebral and suprasellar meningiomas are considered together, the average length of life is seventy-six and one-half months and the average period of usefulness is fifty-three months.

Acoustic Neuromas—These cases, eleven in number, are a particularly difficult group to evaluate. Seven of the eleven patients are alive and four have died. Of the seven living, four are in "excellent condition and able to go about their usual duties. Two others are able to do house work," although remaining blind. Both had practically total loss of vision on entry. The remaining one is able to be about and enjoys life, though handicapped by ataxia and cranial nerve palsies. The

average of useful life is estimated at sixty-one months. The average length of life is 83.4 months.

Blood Vessel Tumors—Four cases comprise this group, in which the patients lived an average of sixty-five months, with a useful period of thirty-eight months. One of the four is now living.

If one considers the encapsulated tumors of the brain and the blood vessel tumors as a group, the average length of life following operation is 76.4 months. The average period of useful activity is 59.3 months.

Metastatic Carcinomas of the Brain—Four patients in this group lived an average of thirteen months. The period of useful living was about three months.

Heterotopia of Cerebellar Tonsil—One instance of a congenital enlargement of a cerebellar tonsil was seen. This anomalous tonsil of the cerebellum extended down the spinal cord to about the level of the third cervical body. Apparently the enlarged cerebellar tonsil was only one of a number of congenital defects. The symptoms for which she came to the hospital, i.e., vertigo and fainting spells, have persisted following the removal of this accessory tissue, the period of useful living is considered nil. The survival period is at least seven years.

COMMENT

A half century or so hence the picture of the surgery of brain tumors, as formulated by the review of the foregoing cases, may well be looked on in much the same light that brain surgery of fifty years ago is looked on today. During the past twenty-five years the surgical technique of various procedures has been fairly well standardized. Much, however, remains yet undone.

A new form of treatment for the rapidly growing primitive cell type of glioma typified by the glioblastomas and medulloblastomas must be sought for and found if the period of "useful activity" is to be of a reasonable duration. The end result of the treatment of the encapsulated tumors—the congenital cysts, the meningiomas and the acoustic neuromas—is almost in direct proportion to the promptness and diagnosis and treatment after the first symptoms. With competent surgical measures a very considerable period of "useful activity" is assured and undoubtedly will be increased as years go by. The cerebellar gliomas, astrocytomas, are very favorable and, in fact, lead the list in this report. While there will always be a certain group of cerebral gliomas which, by right of their location or inaccessibility or growth potentialities will carry with them a very short period of "useful activity," their number should be constantly diminishing. If one is inclined to comparisons, I believe it may fairly be said that surgery of brain tumors suffers not at all, and in fact stands out, as compared to that of tumors of the long bones, breast, stomach, esophagus and rectum. In view of the fact that twenty-five years ago brain tumors were almost universally considered a hopeless lot the periods of "useful activity" here recorded lend a great deal of encouragement and hope for what may be accomplished during the next twenty-five years.

SUMMARY

In this series of 149 brain tumors there were eighty cases of glioma. These patients lived an average of 38.8 months following operation. The period of useful activity of the group is estimated to be 24.4 months.

There were fifty-nine examples of encapsulated tumors of the brain and four instances of blood vessel

tumors This group of sixty-three cases has a survival period of 76.4 months and a period of useful activity of 59.3 months

Four patients with a metastatic brain tumor lived an average of thirteen months, with a useful period average of three months

One patient with a congenital heterotopia of the cerebellum has lived eight years, with a useful period estimated as nil

One patient with a pinealoma died following an operation directed toward its removal

NOTE—I particularly would like to emphasize the fact that any such report as this has depended almost entirely on the very complete follow up of cases. This has meant an immense amount of labor for Dr. Louise Eisenhardt and the staff of the record room of the Peter Bent Brigham Hospital. The patients were a scattered lot from all over this country and Canada with changing addresses. In spite of this only one patient has been lost track of and that through the refusal of relatives to answer inquiries.

I am indebted to Dr. Harvey Cushing for permission to make this report and for the suggestion that I do so.

THE SURGICAL TREATMENT OF INGROWN TOENAILS

E. LAWRENCE KEYES, MD
ST. LOUIS

Two impressions are gained from this study of the operative treatment of ingrown toenails: first, that the rate of recurrence of ingrowth of the nail following operation is unduly high, and, second, that the rate of healing of many of the operative wounds is unduly prolonged. The rate of recurrence was 13.6 per cent in 110 operations. The operative wounds required on the average, nineteen days to heal.

This survey seems to be a fair index of current operative treatment of ingrown toenails, since it comprises 110 operations performed by twenty-six different surgeons in three affiliated institutions in St. Louis. My private cases also are included.

Recurrences were attributed either to the performances of an operation inadequate in type or to failure at operation to remove the necessary amount of nail-bearing matrix¹ or of nail wall. No recurrence could be ascribed to growth of new nail from eponychium. Since the eponychium ordinarily was not excised at operation, this structure would seem to lack the nail-forming function attributed to it by some authors.²

A comparison has been made in the accompanying table between the results of operations of various types.

The usual³ type of operation A, consisted in excising a strip of nail about 0.5 cm. (one-fourth inch) wide and as long as the remaining nail, together with the entire underlying nail bed and nail matrix. Usually some of the nail wall and the ulcer of the nail wall caused by the ingrowing spike of nail were included in this wedge of tissues excised. The wedge was carried down to the periosteum of the terminal phalanx and included all nail, matrix and surrounding soft tissues

beneath the eponychium. The wedge ended proximally very near the interphalangeal joint.

This operation was based on the principle of permanently removing all the ingrowing portion of nail and the redundant nail wall as well. It was founded on the assumption that nail ingrowth was caused by excessive width or convexity of the toenail and by hypertrophy of the nail wall. Recurrences took the form of thin new nail growing again in the old position, or of horns or islands of new nail piercing the old eponychium at one side of the toe. Such new nail grew from cells of the nail matrix the removal of which had not been accomplished.

Sixty operations of type A yielded three recurrences. Only one other type of operation, that of permanent excision of the entire nail and matrix (D) showed better results, and the latter operation was performed only three times because it was considered unnecessarily radical.

The average time for healing of the operative wounds following operation A was sixteen days. This time was one day more than was required by operation B. However, three of the wounds following operation A healed by primary union and required dressing for only six days.

Relief of pain followed operation A in two and one half days on the average, whether the wound healed

Results of Operations for Ingrown Toenails

Type of Operation	Number of Operations	Number of Recurrences	Percent age of Recurrences	Number of Known Cures	Time for Wound Healing Days	Time Until Pain Was Relieved Days

Total	110	15	13.6	38	19	0

* Primary union was obtained in three of these cases. These wounds were dressed only for six days and pain disappeared from them in two and one half days.

by primary or by secondary intention. Operation B required seven days for relief of pain.

The Winograd⁴ operation, here called operation B, consisted in excising or curetting away the nail-forming matrix. A small incision through the eponychium furnished the necessary exposure. A strip of ingrowing nail was removed, similar in size to the strip removed in operation A. The ulcer of the nail wall was usually left intact but sometimes was curetted or excised.

This operation was based on the principle of permanently removing all the ingrowing portion of nail. It was founded on the assumption that ingrowth of the toenail was caused only by excessive width or convexity of the nail, and not at all by overgrowth of the nail wall. Recurrences following operations of this type were of the same character as those following operations of type A. They were due to failure to remove enough nail matrix, and possibly also to a heaping up of the remaining nail wall.

Thirty-four operations of type B yielded four recurrences, a recurrence rate more than double that of operation A. The average time for the healing of operative wounds following this operation was fifteen days, one

day less than the time for operation A. Relief of pain occurred on the average seven days after operation.

The operation of nail avulsion, C, consisted in stripping off all the toenail or merely its ingrowing portion. The nail matrix was not touched, so that an entire new toenail grew in within two or three months. The basic principle of this operation was that the ulcer of the nail wall would completely heal during the time required for new growth of the nail and that subsequent ingrowth and ulceration either would not occur or might be prevented. It was here assumed that minor corrective procedures could inhibit ingrowth of the new nail and that excessive width and convexity of the nail and hypertrophy of the nail wall had no part in causing the ingrown toenail in the first place. Ingrowth of the toenail following operations of this type indicated the fallacy of this assumption.

Nine operations of type C were performed and were followed by seven recurrences. The wounds of two toes that were cured by this method required over a month to heal. At least one patient was made worse by this operation. On her toe the new nail that formed following operation grew in not only at the original site but also all along the advancing edge of the nail. The entire tip of the toe became enlarged and was made worse by an unsuccessful attempt at cure by nail avulsion. It was then necessary to resect a wedge from the tip of the toe in order to restore the normal size, in addition to performing the usual operation at the site of original nail ingrowth.

Complete excision of the toenail and matrix, operation D, is self explanatory. By it the nail was permanently removed. Three operations of this type were performed without a recurrence.

Operation E denotes plastic procedures on the nail wall. In one type of operation the ingrown portion of the nail together with the ulcer and some of the nail wall was excised by one slice of the knife.⁵ The principle of this operation was the permanent removal of the ulcer and of sufficient nail wall to allow the new nail to grow freely. The one operation of this type proved a failure. In the other type of operation⁶ a wedge was resected from that part of the nail wall to one side of the ulcer. The wedge was cut from tissues not actively infected, and primary union was obtained. The ingrowing nail, ulcer and nail wall were not touched. This operation was based on the principle that a decrease in the size of the nail wall would subsequently allow free growth of the nail. It was assumed that ingrowth of the nail was due chiefly to hypertrophy of the nail wall and in small part to excessive width and convexity of the nail. The three operations of this type were successful, but the patients were observed only for a few weeks.

All the recurrences of this series required another operation for cure.

The theoretical basis for recurrence of ingrown toenails has been discussed. In actual practice recurrences were often due to difficulties of technical procedures. Chief among these difficulties were insufficient local anesthesia and inadequate hemostasis.

Insufficient local anesthesia allowed painful stimuli to reach the patient and rendered the careful performance of a thorough operation difficult. Of course general anesthesia was often used in this series but local anesthesia was employed much more frequently. Inadequate

local anesthesia usually resulted from failure to anesthetize the two plantar digital nerves of the toe. These nerves, the plantar digital and not the dorsal digital as is so often believed, are the sensory nerves of the entire nail, nail walls, nail bed, nail matrix and eponychium. Proper anesthesia of the plantar digital nerves always produced satisfactory anesthesia. These nerves were best blocked by injection along the body and flexor aspect of the proximal phalanx. In a few instances a little additional procaine hydrochloride solution (or an appropriate substitute) was injected into the skin between the eponychium and the joint to block off the ramifications of the dorsal digital nerves, which end at a varying distance just beyond the interphalangeal joint.

Inadequate hemostasis obscured structural details in the operative field and consequently rendered identification and excision of the necessary amount of nail matrix more difficult. Some authors⁷ believe that the application of a tourniquet to the base of the toe is unnecessarily painful. This was not found to be the case when local anesthesia was adequate and when it was injected before the tourniquet was applied. In applying a tourniquet, care should be exercised to prevent the occurrence after operation of gangrene of the digit.⁸ This may be done by using a broad tourniquet such as a broad elastic band, placed over a strip of sterile gauze about 1 cm (one-half inch) wide, which has previously been wrapped around the base of the proximal phalanx of the great toe. Such a tourniquet should not be left on for more than half an hour at a time without loosening. The usual operation, even if performed on the two sides of the same nail, rarely required more than half an hour to perform.

It is not my aim in this paper to advocate any particular type of operation. Rather an attempt has been made to point out some principles underlying various operations. An understanding of principles, together with personal preference and experience, will be the sure guides followed by the individual surgeon for the individual case. Better results than these may be expected in the future, up to now, reports of a followed series of cases could not be found in the recent literature.

A means of diminishing the period of convalescence was suggested by this study. One means was the performance of the Winograd operation strictly according to directions.⁴ Another was the attainment of primary union following the usual operation.

Primary union often followed bold clean excision *en bloc* of the necessary tissues, cutting well away from the ulcer and, as far as possible, keeping the ulcer as the center of tissue excision. By properly planning the lines of incision, one could accurately coapt the edges of the wound, leaving no raw surfaces exposed. The lips of the wound were retained by a superficial (not buried) silk mattress suture passing from the nail wall to the soft tissues beneath the nail. Another suture approximated the eponychium, and both sutures were left in place for at least five days before removal.

One important detail for insuring primary union was the prevention, as far as possible, of bleeding or exudation into the wound. This was best accomplished by avoiding attempts to clamp and ligate bleeding points and by securing hemostasis by pressure instead. For this purpose the wound was sutured and a tight sterile gauze pressure bandage applied to the toe before the

⁸ Garlock, J. H. *Gangrene of the Finger Following Digital Nerve Block Anesthesia*. *Ann. Surg.* 94: 1103-1107 (Dec.) 1931.

tourniquet was removed. The toe, bandaged in this fashion, was left elevated on two pillows while the patient lay supine for some thirty minutes directly following operation. The blood soaked dressings were then carefully removed with sterile dressing forceps and discarded. A small square of sterile petrolatum gauze was fitted over the incision and the toe bandaged fairly snugly with fresh sterile gauze. This dressing was left undisturbed for at least three days, unless signs of infection appeared. At that time the gauze superficial to the petrolatum gauze was replaced (painlessly!) by some sterile gauze and left until time for removal of the sutures. By avoiding wet soaks and ointment dressings postoperatively, much secondary infection, both pyogenic and fungous, as pointed out by Dr. Warren H. Cole, was prevented. By not packing the operative wound, healing was hastened, pain minimized and primary union encouraged. By the interposition of the small square of petrolatum gauze between the incision and the dry dressing gauze, much of the discomfort and sticking of the first dressing was avoided. Rest in bed for the first two or three days following operation promoted primary union. Careful antiseptic preparation of the toe the night before operation followed by the application to the toe of a sterile dressing also promoted primary union after operation.

It was surprising how little postoperative reaction followed operations through fields that seemed highly infected. Rarely did the temperature after operation exceed 100 F by mouth, and systemic reactions were absent except in one patient. In a man, aged 70 with diabetes, cellulitis of the toe and foot developed following incision and drainage of an abscess of the wall about an ingrown toenail. The cellulitis subsided following hospitalization for four weeks, with rest and hot soaks and regulation of diet supplemented by the administration of insulin. In most instances, however, it appeared that enough local tissue immunity had been initiated by a chronic local cellulitis to allow for a fair chance of postoperative primary union. The rich blood supply of the toe was a great aid in this.

Complications other than cellulitis did not occur in this series. Osteomyelitis or septic arthritis was never observed, and there were no deaths. Debility, dirt and diabetes initiated and maintained a number of the ulcers of the nail walls.

Women comprised three fourths of the patients of this series. Their tight shoes and high heels thrusting the body weight forward and down into the toes were obvious factors causing ingrowth of toenails. Obesity and pregnancy caused contributory causes, as did occupations involving much walking. However, the toes of many patients were observed to be unusually wide, with thickened nails. These may have resulted from congenital influences or have represented mere end results of chronic irritation and inflammation.

The average age of the patients of this series was 25 years, and the youngest was 6 years old.

The great toe was the site of ingrowth except in one instance, in which the second toe was affected. Unilateral involvement exceeded bilateral as two to one. Ingrowth on the right toe exceeded ingrowth on the left as four to three. Ingrowth of one margin was more common than ingrowth of both margins. Two patients became so absorbed by the pain of the preponderating ulcer as to overlook ingrowth of a toenail elsewhere. The relief of pain consequent to operation

led to a subsequent request for operation on the remaining ingrown nail in each instance.

Some ingrown nails caused by bone tumors and soft tissue tumors were not included in this series.

In severe cases, the immediate performance of an operation at the time the patient was first seen was often possible, and usually advisable. Sometimes a few days' delay with rest, hot soaks and the like ameliorated a severe cellulitis. Operation, however, was performed only when the usual palliative measures, attempted for a week or two, had failed. Few patients required hospitalization.

Beaumont Medical Building

ASEPTIC MENINGITIS FOLLOWING DIAGNOSTIC LUMBAR PUNCTURE

INDICATIONS FOR LUMBAR PUNCTURE AND COMPLICATIONS SECONDARY TO IT

KENNETH E. REYNOLDS, MD

AND

GEORGE WILSON, MD

PHILADELPHIA

The examination of the spinal fluid has become almost as routine a procedure in the diagnosis of neuropsychiatric problems as that of the blood in internal medicine. When the great amount of valuable information made available to the diagnostician is considered, an occasional unfortunate sequel may be forgiven, especially if an effort is made to prevent its recurrence. The most common disabling event, the result of a lumbar puncture, is the headache, neck ache and vertigo that frequently ensue, particularly if a large needle is used and the patient is permitted to go about his business in a few hours. Temporary meningitic signs are sometimes observed, probably resulting from an outpouring of the cells into the subarachnoid space. It is known that a second lumbar puncture performed some hours after a diagnostic tap will show an increase of lymphocytes and albumin in the spinal fluid. Furthermore, if the tap has resulted in the puncture of a vessel, the resulting blood in the subarachnoid space may cause an outpouring of white cells, and meningitic signs. For example, blood in the spinal fluid the result of spontaneous subarachnoid hemorrhage produces stiff neck and Kernig's sign.

The danger of lumbar puncture in a patient suspected of harboring a cerebral neoplasm has been greatly overestimated, particularly in that group lacking roentgen evidence of increased pressure and presenting normal eyegrounds. In the ordinary case of brain tumor with headache, choked disk and the other symptoms there is no occasion to do a spinal tap. Sudden death, respiratory failure, stupor and convulsions have been known to occur after a spinal tap in a patient with a brain tumor, especially if it is located in the posterior fossa, but the same things may happen when no puncture has been done. Nevertheless, a tap should not be done in a patient with a posterior fossa neoplasm or in a cerebral abscess when a real danger exists, in that a meningitis may be produced and even rupture of an incompletely walled off abscess occur.

Read at a meeting of the Section on Medicine, College of Physicians, Philadelphia, March 26, 1934.
From the Philadelphia General Hospital and from the Neurological Department of the University of Pennsylvania School of Medicine.

Ayer and Felton and others have shown in experimental animals infected with various organisms that meningitis may be produced by the mere withdrawal of spinal fluid. One should be very loathe, therefore, to do a diagnostic tap on patients ill with acute infections, such as scarlet fever or pneumonia, who present meningitic symptoms.

It is usually unnecessary to withdraw fluid for study in the ordinary patient with a cerebral accident, but if the relative youth of such an individual might lead to the suspicion of syphilis, enough fluid may be taken to permit laboratory tests. Occasionally a slight cerebral hemorrhage is made to rupture into the ventricles by the removal of fluid.

We have never observed any aggravation of neurosyphilis by a spinal tap, although others have. On one occasion we gave a patient with cerebral syphilis a note admitting him to a hospital for examination of the spinal fluid. Before he reached the hospital he had an attack of cerebral thrombosis which resulted in permanent hemiplegia, had this been delayed twenty-four hours, the spinal tap would have been blamed and a possible medicolegal complication would have been in the offing.

An unusual result which we saw a few years ago was death an hour after a spinal tap, Queckenstedt test and the removal of a few cubic centimeters of fluid from a patient who had an extradural abscess in the thoracic region secondary to pneumonia and empyema. This may have been a cardiac death, but it occurred shortly after a spinal tap.

The advisability of drawing off spinal fluid in a traumatic case with subarachnoid blood has been questioned, as has it also in spontaneous subarachnoid bleeding. Our own practice has been to do it especially in the spontaneous bleeding case. We¹ have reported a series of such cases in which good results ensued. A contraindication would exist if the subarachnoid bleeding should be due to a leaking aneurysm, although even then a temporary cure may be effected. In a colored woman taken acutely ill and brought to our service at Blockley, Weber's syndrome with signs of meningitis existed. The tap revealed bloody fluid, the punctures were repeated daily until it was thought that no fresh bleeding was occurring, the patient recovered the use of the paralyzed side and partly that of the third nerve. She worked around the ward for some weeks, had a recurrence and died within a few hours. Necropsy showed a ruptured aneurysm of the circle of Willis. Blood in the subarachnoid space acts as an irritant, may produce adhesions and "arachnoiditis," may cause stupor, fever and signs of meningitis, and in our opinion should be removed whether the result of trauma or of spontaneous bleeding.

If lumbar puncture is performed under aseptic technique with the patient on his side, a small bored needle used, a local anesthetic given, and a sedative if the patient is "nervous," and obvious cases of brain tumor and abscess avoided, very few accidents will happen. A syringe should never be used to aspirate the fluid. The breaking off of a needle in the patient's back may occur, if he moves suddenly and (or) if the needle is defective and partially rusted through. The needle should be tested by bending before it is inserted. The patient should always rest in bed for from twelve to twenty-four hours after a tap, although many physicians per-

form lumbar punctures in the office and send the patient out in a short time.

We have had three cases in which lumbar puncture was followed by fever, stiff neck, Kernig's sign, stupor, delirium and a pronounced increase of cells in the spinal fluid, without the discovery of organisms in the fluid by smear and culture, and without a reduction in the amount of sugar normally present. Spiller and Payne reported a case similar to these in 1924, after a puncture in a case of epilepsy. The diagnoses in our cases were cerebral syphilis, chronic encephalitis, and a fibroblastoma in the frontal region without the general symptoms of a tumor. Such a complication is unique, and we report our observations.

REPORT OF CASES

CASE 1—B. R., white woman, aged 47, was admitted to the neurologic service of the Philadelphia General Hospital, Jan. 24, 1934. A lumbar puncture was performed on January 29 with

TABLE 1—Cerebrospinal Fluid Examinations in Case 1

Date	Color	Cell Count	Smear	Culture	Sugar
1/30/34	Cloudy	2,900 95% poly morphonuclears	Negative for organisms	No growth	59
1/31/34	Cloudy	459 80% poly morphonuclears	Negative for organisms	No growth	Not done
2/1/34	Cloudy	100 60% poly morphonuclears	Negative for organisms	No growth	60
2/2/34	Cloudy	290 80% poly morphonuclears	Negative for organisms	No growth	Not done
2/3/34	Clear	No examinations made			
2/4/34	Clear	120 16% poly morphonuclears	Negative for organisms	No growth	60

TABLE 2—Cerebrospinal Fluid Examinations in Case 2

Date	Color	Cell Count	Smear	Culture	Sugar
1/30/34	Cloudy	3,780 90% poly morphonuclears	Negative for organisms	No growth	Not done
1/31/34	Cloudy	2,610 90% poly morphonuclears	Negative for organisms	No growth	64
2/1/34	Cloudy	360 50% poly morphonuclears	Negative for organisms	No growth	67
2/2/34	Cloudy	236 50% poly morphonuclears	Negative for organisms	No growth	62

2/4/34	Clear	14 All lymphocytes	Negative for organisms	No growth	Not done

the following results: cell count, none; globulin trace; Wassermann reaction, 4 plus; colloidal gold curve, 5444433100. Twelve hours later she became delirious, was semistuporous, complained of headache, and had a temperature of 104.5. The neck showed extreme rigidity with some retraction of the head. A bilateral Kernig sign was present. The white count was 6,800. The examination otherwise was negative. Spinal punctures were done on six succeeding days with the results given in table 1.

The temperature gradually came down to normal by the fourth day, the meningitic symptoms had disappeared by this time. The patient said two weeks after the original puncture that she had improved greatly since her admission.

CASE 2—A. Negress, aged 35, was admitted to the neurologic service of the Philadelphia General Hospital Jan. 8, 1934, ill with a far advanced state of parkinsonism, the result of chronic

¹ Meltzer, Joseph, and Wilson, George. Spontaneous Subarachnoid Hemorrhage. J. A. M. A. 93: 89-93 (July 13) 1929.

epidemic encephalitis. A diagnostic lumbar puncture was done January 29 by the same intern who performed it in case 1 and immediately thereafter, but with a different needle. About ten hours later she was delirious, had well marked signs of meningitis, and the temperature was 102.4 F. The white count the following day was 5,400.

The diagnostic tap revealed a normal spinal fluid. The fluid examinations for the succeeding six days were as shown in table 2.

The patient recovered more slowly than patient 1 but within a week had fully recovered from the effects of the meningitic reaction. She died three weeks later as the result of chronic encephalitis.

CASE 3—A white man aged 43, was seen by us as a private patient, Sept. 2, 1926. A diagnostic tap was done on September 5 at 9:45 a. m. At 5:45 p. m. he complained of headache, neckache and vomiting. At 11:30 p. m. he had rigidity of the neck, spastic extremities and a temperature of 103 F. He developed herpes labialis. The white cell count was 13,840. The results of subsequent examinations of the spinal fluid are given in table 3.

The man recovered completely from the meningitic state within four days. He later had a benign tumor removed successfully from the left frontal region.

TABLE 3—Cerebrospinal Fluid Examinations in Case 3

Date	Color	Cell Count	Smear	Culture	Sugar
9/ 6/26	Turbid	2,610	Negative for organisms	No growth	Not done
9/ 7/26	Turbid	17,670 87% poly morphonuclears	Negative for organisms	No growth	Not done
9/ 8/26	Turbid	10,500	Negative for organisms	No growth	Not done
9/ 9/26	Less turbid	3,020	Negative for organisms	No growth	Not done
9/10/26	Slightly cloudy	203	Negative for organisms	No growth	Not done

COMMENT

The term aseptic meningitis seems justified because no organisms were found, and the spinal fluid sugar, which practically always decreases in amount or actually disappears in ordinary meningitis, remained normal in the two cases tested. All three patients, as also the patient cited by Spiller and Payne, recovered. The patient with brain tumor was subsequently operated on successfully, the woman with cerebral neurosyphilis was actually benefited by the experience, and the patient with chronic encephalitis was not permanently affected but died later of chronic encephalitis.

The manner in which the picture is produced is uncertain. Perhaps some particulate matter left in the needle after "cleaning" may bring forth an outpouring of cells and in that way produce the condition. Spiller and Payne² thought that in their case the meningeal vessels were congested from repeatedly occurring fits (the patient had epilepsy) and that, as the result of relief or pressure, cells escaped into the subarachnoid space. Any foreign substance introduced into the spinal fluid may bring about an aseptic meningitis. Thus, serum or even improperly prepared salt solution or drugs may induce a train of meningitic signs when injected into the spinal subarachnoid space. Drainage of the spinal fluid on two or three successive days seemed to be curative in our patients, perhaps they would have recovered without the taps.

BROMIDE INTOXICATION

J. C. SHARPE, MD

BALTIMORE

As a clinical entity, bromide intoxication has been recognized for some time by the psychiatrists. However, it is not infrequently observed in a general medical service and may give rise to some very puzzling diagnostic problems.

Bromides were discovered by Balard in 1826 and introduced later into therapy by Graf in 1840.¹ The first case of bromide intoxication was reported by Huette² in 1850. In 1901, Landenheimer³ was the first to recognize the important influence of the intake of chlorides on the retention of bromides. More recently Wuth,⁴ in a six months period at the Henry Phipps Psychiatric Clinic of the Johns Hopkins Hospital, reported twenty cases of bromide intoxication that occurred among 238 admissions. Wagner and Bunburg⁵ stated that in 1,000 consecutive patients admitted to the Colorado Psychopathic Hospital, forty-four showed the presence of bromides in the blood, and in seventeen of these the mental symptoms were due solely to bromidism. In a series of seventy-seven patients with a blood bromide above 75 mg. per hundred cubic centimeters, for 48 per cent the drug was prescribed by a physician and in 18 per cent the source was a proprietary medicine. Their patients were for the most part "that type of individual who is unable to make an adequate social adjustment and who resorts to alcohol and drugs as an escape from situations in life which he considers intolerable." Among those who had an underlying psychosis, the largest group were psychoneurotic patients and the next largest group were manic depressive patients. Doane and Weiner,⁶ reported four cases of bromide intoxication admitted to a general medical ward. Harris and Hauser⁷ considered that bromide intoxication must be thought of in the diagnosis of any patient who shows an acute organic type of reaction, and that the symptoms of the condition will vary with the personality make up and with toxic factors. Sippi and Bostock⁸ reported recently nine more cases and emphasized the fact that only one was associated with a dermal eruption. Diethelm,⁹ in an excellent and comprehensive review of the literature, described nine cases of his own and stated that 40 per cent of the patients admitted to the Phipps Psychiatric Clinic during the course of a year had taken bromide, but only 2 per cent showed toxic symptoms (0.5 per cent simple intoxications, and 1.5 per cent delirious reactions). Wainwright¹⁰ reported five cases of bromide intoxication and concluded that these untoward effects make bromides no less valuable

as therapeutic agents but do stress the importance of their intelligent use, without which the distressing and often bewildering manifestations of intoxication appear.

Solomon¹¹ described the pharmacologic action of the bromides as follows. They depress the entire central nervous system, with the exception of the medulla, depressing the psychic functions, the motor cortex and the spinal cord—lowering its reflex excitability. The muscle tone is lowered throughout the entire body. Ordinary doses have no effect on the circulation, but larger doses depress the heart and vasoconstrictor center. They lessen arterial tension and lower body temperature, depress sexual appetite and power, and cause pallor, acne on the face and extremities, coated tongue, disordered digestion, emaciation, somnolence, sluggish reflexes and defective coordination. They may be responsible for impairment of the mental faculties, with hallucinations and delusions, or cause melancholia or maniacal excitement.

Bromides are not excreted by the kidney as rapidly as chlorides, but they tend to be retained in the blood, replacing partially the chloride ion. Symptoms of intoxication generally appear when from 25 to 30 per cent of the chloride ion is replaced by the bromide. According to Bernoulli¹² a replacement of more than 40 per cent of the chlorides of the blood by the bromides is fatal. There seems to be a great variability in the individual susceptibility to bromide. The amount of chloride intake in the diet may account for some of this variability. In addition, arteriosclerosis, alcoholism, anemia, cachexia and syphilis seem to predispose to retention of bromide.

Clinically, the picture of bromide intoxication is protean. Anorexia, constipation and loss of weight may be the first symptoms. Sleep may be disturbed. Bromoderma and conjunctivitis may develop. Symptoms of mental dulness, confusion, disorientation and defective memory for recent events are common and may progress to stupor and coma. Now and again there may be a delirious state characterized by delusions and hallucinations, the latter especially of the visual type and characteristically of colored animals. Ideas of persecution or marked fear may predominate. The patient may be depressed, irritable or even maniacal.

The temperature may vary from normal to 103 F. Usually the pulse is rapid. An eruption may or may not develop. The pupils may be unequal and react to light only sluggishly. The speech is thick and unintelligible, the tongue is coated, and swallowing may be difficult. There may be a coarse tremor of the lips and hands. Difficulty in walking may be the chief complaint and there may be gross ataxia. The deep reflexes may be diminished or absent, and sensibility to touch and pain may be lost.

During a period of three years, ten patients suffering from the symptoms of intoxication from bromides have been admitted to the private medical service of the Johns Hopkins Hospital. In each it was difficult to determine the exact nature of the syndrome that was responsible for the admission of the patient until a blood bromide determination gave the clue as to the true type of reaction. A history of taking bromides may be difficult to elicit because of the patient's mental confusion or because of his ignorance of the presence of bromides in the medicine he has taken.

REPORT OF CASES

The following abstracts give only the salient points in each case.

CASE 1—F. W., a married housewife, aged 38, entered the hospital because of severe, recurrent attacks of bronchial asthma. She had sought relief at a number of clinics and had taken morphine, epinephrine and ephedrine with no improvement. On admission she presented the typical signs and symptoms of bronchial asthma. In addition, her face was flushed, her tongue was heavily coated, and her speech was thick and difficult to understand. She was somewhat disoriented as to time and place, wept occasionally and at times was somewhat delirious. Three days after she entered the hospital an acute maniacal reaction developed. She cried "I must be losing my mind" and "I cannot think straight," and on one occasion she was heard to say that she was really not a Negro. The psychiatric consultant discovered that she had been taking daily 15 grams (1 Gm.) of triple bromides every two hours for three weeks before admission, and examination of the blood showed the presence of 300 mg of bromide per hundred cubic centimeters. She was given 9 Gm of sodium chloride a day and her mental state improved promptly. She was discharged after three weeks in the hospital at which time the blood bromides were 50 mg per hundred cubic centimeters.

CASE 2¹³—R. M., a man aged 46, a dentist, entered the hospital with a preliminary diagnosis of an atypical encephalitis. He had had a chronic arthritis for twenty years, but in spite of his deformity he had carried on his work in a satisfactory manner. A month before admission the patient had taken to bed because of progressive weakness. Three weeks before admission a lumbar puncture had been done because of some vague neurologic signs following which the patient became completely disorientated, muttered unintelligibly and became uncooperative and at times violent. He was brought to the hospital for diagnostic study. His temperature ranged from 100 to 102. The general physical examination was essentially negative except for an erythematous eruption over the face and back that had been present for several months. The neurologic examination showed hyperactive reflexes and some spasticity of the lower extremities. The speech was slow, thick and rambling. A lumbar puncture yielded a perfectly normal spinal fluid. Again following this procedure he became acutely delirious. Further inquiry indicated that he had been addicted to the use of Bromo Seltzer for several years and had been taking a great deal in recent weeks. The blood bromides were 300 mg per hundred cubic centimeters, and spectroscopic examination for methemoglobin was negative. Sodium chloride therapy was instituted and four days later the temperature became normal and there was marked clearing of the mental state. He was discharged one month after admission. The blood bromides were 50 mg per hundred cubic centimeters.

CASE 3¹³—A. W., a married housewife, aged 58, entered the hospital in an unconscious state. The preliminary diagnosis was a metastatic brain tumor. Six years previously a radical amputation of the left breast had been performed for cancer. A year before admission the patient had received minor lacerations of the scalp as the result of an automobile accident. The present illness began five weeks prior to entrance with a constant dull suboccipital headache, dimness of vision, diplopia and difficulty in walking. For four days she became increasingly drowsy and uncooperative. The speech was thick, the tongue was furred and she complained of difficulty in swallowing. There was slight bilateral papilledema, diminished reflexes of the leg and a positive Babinski reflex on the left side. A ventricular tap was done and bloody fluid was obtained under normal pressure. Because of the poor condition of the patient she was sent back to the ward and saline infusions were given. A lumbar puncture revealed a normal spinal fluid. It was learned from the patient's Negro maid that the family physician had prescribed a bromide mixture to be taken one teaspoonful four times a day because of nervousness that had developed following the automobile accident a year previously.

¹² Bernoulli, E. Zur Dosierung der Bromsalze bei Epilepsie und Depressionen. *Cor. Bl. f. Schweiz. Aerzte* 47: 102 (Aug. 11) 1917.

¹³ Cases 2 and 3 were previously reported by Wainwright.¹⁴

The patient had taken the bromide mixture regularly as directed. On account of some vague hallucinations and delusions two months before admission, the physician had increased the dose to every three hours. A blood bromide determination was 250 mg per hundred cubic centimeters. The saline infusions were continued, clinical improvement followed rapidly, and recovery was established within a month with complete disappearance of the neurologic signs and a decrease of the bromides of the blood to 25 mg per hundred cubic centimeters.

CASE 4—C T, a married housewife aged 61 entered the hospital in a confused disoriented state with a preliminary diagnosis of bulbar disturbances and peripheral neuritis. Six months before entrance she had suffered an attack of "phlebitis" and was required to spend several weeks in bed. During her convalescence she had fallen and twisted her ankle, following which she noted difficulty in walking, numbness and tingling of the hands and feet and extreme weakness. Her physician prescribed some medicine containing bromide to be taken three times a day. Two months before admission the patient's family noted that she was somewhat confused, that her memory was poor and that her speech was indistinct. Incontinence of urine and feces developed gradually and the patient sank slowly into a stuporous condition. On examination she was markedly undernourished and stuporous, she was picking at the bedclothes muttering incoherently. There was a coarse tremor of the head, lips and hands. The reflexes of the upper extremities were barely elicited and those of the lower ones were absent. There was considerable tenderness of the calf muscles. The blood showed a macrocytic type of anemia of marked degree that was characteristic of pernicious anemia. There was no free acid in the gastric contents even after stimulation with histamine. The spinal fluid was normal. The blood bromides were 175 mg per hundred cubic centimeters. She was given daily intramuscular injections of liver extract and infusions of physiologic solution of sodium chloride and in spite of bronchopneumonia that developed in both lower lobes she improved rapidly, becoming oriented and mentally clear within twenty-four hours. However, following the excretion of the retained bromides she was found to have signs of combined degeneration of the spinal cord and was kept in the hospital for two months. Although she received intensive liver therapy only moderate improvement of the neurologic signs was noted.

CASE 5—S W, an army officer, aged 53 entered the hospital in a very confused state of mind giving a long history of "adhesions," constipation, and pain in the lower left part of the abdomen. In 1921 carcinoma of the colon developed, which was resected, and thereafter several operations had been performed for the release of adhesions. The temperature was 100.4. He was somewhat disoriented, irritable, and at times unresponsive. His speech was low, thick and unintelligible. The skin had a muddy appearance. The tongue was heavily coated and swallowing was difficult. There were facial twitchings and a coarse tremor of the lips and hands. All the deep and superficial reflexes were diminished. At times there were definite auditory hallucinations. He admitted taking bromidin for a long time in increasing doses. The blood bromides were 325 mg per hundred cubic centimeters and intravenous and subcutaneous injections of saline solution were started. Bronchopneumonia developed, but in spite of this the confusion was lessened within three days. Two weeks later, the bromides were 75 mg per hundred cubic centimeters and all signs of the intoxication had disappeared.

CASE 6—M B, a married housewife aged 61, entered the hospital in a semistuporous condition. The initial impression was that the symptom was due to a generalized and cerebral arteriosclerosis associated with a senile psychosis. The history was given by her aged husband and was vague. For eighteen months he had noticed that the patient had some difficulty in walking, that her memory was impaired and that her speech was indistinct. All the symptoms became much more pronounced three weeks before admission with the development of disorientation, emotional instability and finally semistupor. On examination the patient was irritable, and her speech was only a mumble. All her mental reactions were slowed. Her pupils were unequal, the right one reacted to light and the

left pupil was fixed. The tongue was smooth and clean. The deep reflexes were all hyperactive. A bilateral Hoffman's sign, and a positive Oppenheim's reaction on the right side were noted. The station and gait were unsteady. It was found that a practical nurse had instructed the patient to take "Nervine" and for four weeks before admission she had taken three bottles of that preparation. The blood bromides were 300 mg per hundred cubic centimeters. After the oral administration of chloride she improved rapidly and on the fifth day insisted on leaving the hospital, against advice.

CASE 7—R R, a man, aged 50, a railway official, came to the hospital in apparently a profound alcoholic intoxication. It was known that he had been addicted to the use of alcoholic beverages for many years. Because of increased restlessness and nervousness he had consulted a physician three months before admission and had been given some medicine (bromides) to take. A short time later, anorexia and mild, intermittent epigastric pain had developed, and his family had noticed that he was confused at times and often forgetful and that his personality was becoming altered so that he was forced to give up his work. He was semistuporous, confused and disoriented. There was only moderate arteriosclerosis. Articulation was difficult. The movements of the hands were slow and clumsy owing to a coarse tremor. The pupils were contracted and reacted incompletely to light. All the deep and superficial reflexes were diminished. There was tenderness of the calf muscles. The blood bromides were 375 mg per hundred cubic centimeters. He was given daily doses of 6 Gm of sodium chloride by mouth and two weeks later the blood bromides had fallen to 50 mg per hundred cubic centimeters, concomitantly with remarkable improvement of the confusion and neurologic signs.

CASE 8—H M, a man, aged 48, a hose manufacturer, entered the hospital in what was thought to be an acute alcoholic state. He had been a confirmed alcoholic addict for many years, and because of persistent headaches, he had recently taken large amounts of allonal (allylisopropylbarbituric acid with imidopyrine) and "other medicines" for the relief of them. During the four weeks prior to admission there had been a gradual slowing of the mental processes, indistinct speech, unsteady station and gait, and also inability to remember recent events. When he entered the hospital, he was belligerent. The tongue was tremulous and thickly coated. There was a coarse tremor of the fingers. All the reflexes were normally active, and muscle tenderness was noted in the lower extremities. The blood bromides were 325 mg per hundred cubic centimeters. Chloride therapy was started, but because of motor restlessness, hallucinations, ideas of persecution and the generally maniacal reaction that disturbed other patients in the ward he was transferred to a private nursing home, where he made an uneventful recovery in two weeks.

CASE 9—H A, a man, aged 70, the head master of a girl's school, entered the hospital with a preliminary diagnosis of senile dementia. During the preceding few months he had suffered financial losses and had business worries. A few weeks before admission his wife had noted his loss of interest in his business, a tendency to repeat, confusion, disorientation, depression and intense emotional outbursts. There was an increasing unsteadiness of his gait. He slept most of the day but would walk the floor during the night moaning because of vague, fleeting abdominal pains. The physical examination revealed masklike facies, a somewhat rigid, stooped gait, a monotonous tone of voice, and a slight tremor of the extended fingers—manifestations that suggested an early parkinsonian syndrome. The mental confusion and depression were obvious. He admitted that he had been taking bromides on his own initiative for the past few months. The blood bromides were 274 mg per hundred cubic centimeters. He insisted on leaving the hospital after ten days, but during that time his mental faculties improved remarkably, his drowsiness disappeared, and the strength of his legs returned. On discharge, the bromides were 150 mg per hundred cubic centimeters.

CASE 10—M W, a woman, aged 34, entered the hospital with the chief complaints of difficulty in walking and spells of depression. She gave a long, dramatic history, characteristic of an unstable emotional, inferior personality. She had been a chronic alcoholic for years and smoked at least three pack

ages of cigarets a day. The symptoms had become manifest about six weeks before admission, at which time she had consulted her physician for nervousness. He had prescribed bromides, but her nervousness increased in spite of the administration of as much as from 25 to 35 Gm a day. In addition, her sleep was disturbed, she had become unsteady in walking and had fallen several times because of weakness of the legs, she had become confused, disorientated and unable to think clearly, and she had developed spells of depression with uncontrollable weeping. The examination was quite negative except that she was very restless, talked constantly and had a coarse tremor of the hands and lips. The initial bromide determination was only 350 mg per hundred cubic centimeters in spite of the tremendous doses that she had taken. With chloride therapy she improved rapidly, and a week later the bromides had decreased to 175 mg per hundred cubic centimeters.

COMMENT

In review, it is obvious that bizarre symptoms may develop in any given case of bromide intoxication. Ten such cases were admitted to the general medical service. To diagnose the syndrome correctly required the consideration of many states, among them acute or chronic alcoholism, Korsakoff's syndrome, encephalitis, brain tumor, senile psychosis, uremia and dementia paralytica or dementia paralytica with tabes. Of the ten patients in our series, five were men and five were women. The ages varied from 34 to 70 years. The administration of the bromides was initiated in six patients by a physician, in one by self medication, in one by the advice of a nurse, and in two by the use of "patent medicines." Five of the patients had marked delirious reactions, in case 2, on two different occasions, the delirious reaction was precipitated by lumbar puncture. Five presented symptoms of a profound intoxication. Only one patient developed a skin eruption. The other usual symptoms included difficulty in swallowing, a heavily coated tongue, mumbling speech, coarse tremor of the extremities, difficulty in walking, and tenderness of the calf muscles. The initial level of the bromide content of the blood varied from 175 mg to 375 mg per hundred cubic centimeters and in seven instances they were above 300 mg. The discovery of a positive blood bromide reaction in a case of acute delirium or deep stupor modifies considerably what might otherwise be a grave prognosis. Each case showed a remarkable, rapid improvement following the institution of suitable therapy.

The diagnosis is simple. In all suspected cases a test of bromide excretion in the urine is made rapidly and simply and is of sufficient reliability to rule out bromide intoxication. Wuth⁴ describes the procedure as follows: To 25 cc of urine, add 10 Gm of animal charcoal, mix well, allow to stand for a few minutes, and filter. To 5 cc of the filtrate, add 1 cc of 30 per cent trichloroacetic acid and 1 cc of 0.5 per cent gold chloride solution. A brown shade denotes a positive reaction. For the quantitative determination of the blood bromides, the Walter modification of the Hauptmann method is used, which involves the use of blood serum with the addition of gold chloride, producing a color change corresponding to the bromide concentration, varying from a yellowish greenish brown to a red brown. The reaction is specific for bromides except for iodides. According to Wagner and Bunburg, determination of bromide in the spinal fluid is not sufficiently reliable to warrant utilization of that test.

The treatment is supportive and eliminative. All medication containing bromide should be discontinued immediately. If the patient is stuporous or if it is difficult for him to swallow physiologic solution of

sodium chloride should be administered parenterally. However, if this procedure is not necessary, the daily administration of from 6 to 8 Gm of sodium chloride by mouth is indicated. Some authors⁸ warn that it is best not to begin chloride replacement during the first twenty-four to forty-eight hours, as the symptoms may be aggravated by driving the bromides from the tissues with a resultant increased concentration of them in the blood. Fluids given in liberal amounts and a high caloric diet are helpful adjuvants. Following the elimination of the bromides from the system, a study of the underlying personality should be made in order that prophylaxis directed toward the prevention of a recurrence of the syndrome or of the addiction to other drugs may be prevented.

SUMMARY

1 Ten cases of bromide intoxication were observed during a period of three years in a general medical service.

2 Because of the possibility of manifestations of bromide intoxication following the administration of the drug, physicians should be cautious in prescribing bromides for any length of time. This is particularly true of patients with impaired excretory or circulatory functions. The drug should be discontinued immediately with the onset of any unusual symptoms.

3 In patients presenting profound stupor, acute delirium or obscure neurologic symptoms, the presence or absence of bromide intoxication should be determined by simple tests of the urine and blood.

SCIATIC NEURALGIA: A CLINICAL ENTITY

ITS SYMPTOMS, DIAGNOSIS AND TREATMENT,
WITH A REPORT OF SIXTY CASES

EMIL D. W. HAUSER, M.D.
CHICAGO

Sciatica is a reflex neuralgia or a referred pain along the distribution of the sciatic nerve; it should be distinguished from sciatic neuritis, which is an inflammation of the sciatic nerve. The modern attitude, expressed by Feilng,¹ is to think of sciatica as signifying sciatic pain without connoting any particular pathogenesis. DaCosta² states that true sciatica is not a neuritis. Moersch³ believes that differentiation of neuralgia from neuritis of the sciatic nerve is of clinical importance. The usual classification of sciatica into primary, secondary and idiopathic groups is inaccurate and, in view of present knowledge, inadequate. More correctly, one may classify, first, sciatic neuritis or a true inflammation of the nerve, secondly, a reflex sciatic neuralgia or essential sciatica. Before the essential reflex neuralgias are described, it is necessary to classify and discuss sciatic neuritis.

An inflammation of the sciatic nerve may be either primary or secondary. Primary sciatic neuritis is due to a generalized toxemia, as from alcoholism, lead or arsenic poisoning or it may be the result of a systemic disease such as diabetes or syphilis. The secondary

group is likewise a peripheral neuritis but is due to pressure on the nerve usually before it leaves the pelvis as from spinal cord tumors that exert pressure within the canal, or metastatic tumors that press on the sciatic root, plexus or trunk, pelvic tumors may give unilateral pressure on the plexus or nerve.

Putti,⁴ in his description of sciatica, demonstrated a narrowing of the intervertebral foramina due to anomalous articular facets, and arthritis with a resulting impingement on the nerve roots. Craig and Ghormley⁵ have referred to this condition as "facet syndrome." In a similar manner Williams⁶ ascribed a sciatic irritation to a reduction of the lumbosacral space. The reflex neuralgias, however, are of much more frequent occurrence than these two recognized groups of primary and secondary neuritis combined.

Before a reflex sciatica can be diagnosed, sciatic neuritis must be excluded. Unlike sciatic neuritis, the neurologic manifestations in reflex neuralgia are normal. The roentgenogram of the lumbosacral spine and pelvis is negative. Toxemias and constitutional diseases must be ruled out. The diagnosis does not depend exclusively on differentiation from neuritis. There are positive symptoms and observations, the presence of which is certainly suggestive if not conclusive. The sciatica is preceded by symptoms of muscular insufficiency in the lumbar and sacro-iliac region—intermittent ache and tiredness, stiffness and soreness, constant ache, localized boring pain over the lumbosacral angle or over one or both sacro-iliac joints and signs of inflammatory reaction in these joints. At the same time, physical examination during an acute attack shows muscle spasm in the lumbar area, a protective list is present, Lasgue's sign is positive on the side of the affected nerve, the posture, particularly between acute attacks, is poor, the normal curves of the back are increased. In about one half of the cases there are signs of a generalized nervous fatigue and irritability, in some instances this reaches such a degree that neurasthenia is diagnosed. The frequency with which weak feet and varicose veins accompany the neuralgias is regarded as further proof of the presence of physical strain.

A study of these neuralgias and a review of sixty cases led to several interesting conclusions: first, that this condition is not a true neuritis but an essential reflex sciatic neuralgia, second, that the referred pain is not confined to the sciatic nerve, third, that the origin of these pains may be attributed to muscular insufficiency or physical strain and, fourth, that any environmental condition which strains the nervous system acts as a contributing factor.

The following three examples of the cases reviewed show a reflex sciatic neuralgia with typical symptoms and a cure by treatment of the muscular insufficiency.

CASE 1—Sciatica muscular insufficiency. J. H. L., a man, aged 40, a sales manager, was referred for relief from pain over the right sciatic nerve, which had been present for three and one-half months. The pain over the thigh started insidiously and grew progressively worse. Gradually the calf of the leg and finally the ankle and foot were involved. He described the pain as a constant ache with periods of exacerbation. The pain was more severe after prolonged sitting. Five days previous to his examination he drove 100 miles in his car. The

pain became so severe, as a result, that he was unable to sleep. The muscles in the leg cramped periodically. He also complained of low backache. He had had this ache for many months previous to the pain in the leg. There was some stiffness and soreness in the lumbar area. He felt tired even in the morning. Just previous to the onset of the pain in the thigh he was under unusual stress as a result of great business reverses.

Examination revealed that the patient walked with a careful gait. He sat on the edge of his chair. Every few minutes he altered his position. Flexion of the back was slightly limited. The Lasgue sign was positive. The posture of the back was altered so that there was a slight list and some loss of lumbar curve. The laboratory observations were negative. No foci of infection were found.

The patient was hospitalized for six days. Buck's extension was applied. An electric pad was used over the lower part of the back. A reinforced corset was fitted and applied to support the lumbosacral area. Periodic rest was carried out systematically. Graded exercises were prescribed and supervised. The corset was discarded. He was relieved of the symptoms and back at work in two weeks. He remained well and when seen a year later stated that he had had no trouble since the treatment and that he had never felt better.

CASE 2—Sciatica, muscular insufficiency. H. F., a business man, aged 43, who entered Passavant Memorial Hospital May 31, 1932, complained of pain in the right leg. The pain was first noted in January 1932. Previous to that time fatigue had been noticed in the lower part of the back and sacro-iliac region, particularly after driving a car on long trips. The back felt tired and ached, there was a localized spot of pain in the region of the right sacro-iliac joint. There was pain in the lateral aspect of the hip, radiating down the posterior surface of the right thigh and down the lateral aspect of the leg. Stiffness was felt on getting up in the morning. Usually the pain was not severe in the morning but grew worse during the day. He could scarcely walk at the time of examination. There was no history of rheumatism or trauma. In an effort to cure the illness an abscessed tooth had been extracted. He felt generally tired and was unusually irritable. He had used heat, rest and salicylates for relief.

The patient was thin and stood bent forward with a marked list to the left. There was a loss of lumbar curve and marked lumbar muscle spasm. There was localized tenderness over the right sacro-iliac joint, there was also a tender area over the right greater trochanter. Lumbar motion was limited in all directions. Lasgue's sign was positive, markedly so on the right.

Prostatic examination was negative. The urine, stool and blood were normal and the Wassermann test was negative. Blood urea was 15 mg., uric acid 48 mg., and blood sugar 80 mg. The phenolsulphonphthalein test showed from 45 to 50 per cent of the dye excreted in the first hour. A fractional meal revealed free acid, maximum 29, total acid 53. A roentgenogram of the sinuses was negative except for slight clouding of the sphenoids not characteristic of infection. A roentgenogram of the lumbar spine and sacro-iliac region revealed very little lumbar curve, and nothing abnormal was reported.

The patient was put at rest in bed with bilateral Buck's extension, with local heat to the back. In a short time he could rest comfortably on his back. The muscle spasm subsided in five or six days after which a light supportive body cast was applied with the patient in full extension. After three days he became accustomed to the cast so that he could walk around the room, after which he progressed rapidly. The patient was apt in grasping his condition and method of treatment. He left the hospital much improved, able to walk several blocks but he continued to have some pain over the right sacro-iliac joint after exercise. Exercise was gradually increased and periodic rests were slowly decreased. He continued to improve and as he grew stronger the pain disappeared entirely.

Four weeks after treatment he had lost all sense of fatigue. There was no pain in the lower extremity. He has remained well and after a period of two and one half years states that he has never felt better.

CASE 3—*Sciatica and lateral cutaneous neuralgia, muscular insufficiency* Miss H. N., aged 34, a school teacher, nervous, slightly eccentric, entered Passavant Memorial Hospital complaining of an acute sciatica. The pain was intense and coursed down the lateral side of the right thigh and leg. She also complained of intermittent lumbago and low backache, which had been present for four years. She was irritable and worried and seemed tired all the time. The back was stiff on getting up. She obtained relief from backache by rest and the wearing of a support. The pain in the legs, when first noticed, felt like threads of pain going down the lateral side of the right limb. The pain grew worse and became continuous, finally becoming so severe that the patient could not walk. She obtained relief only with constant rest and continued local heat.

The patient was evidently suffering pain. She could not stand erect, when she tried to stand she bent forward and listed markedly to the left. The right leg and thigh showed slight atrophy. There was some lumbar muscle spasm. The outer side of the thigh seemed to be tender to pressure. A mitral regurgitation was present. The Lasègue sign was positive. The blood count and urine were normal, the blood Wassermann reaction was negative. A roentgenogram of the lumbosacral area showed no abnormal changes.

The patient was put to bed with bilateral Buck's extension. Local heat and salicylates were also used. She improved rapidly and was placed in a body cast in a corrected position. She left the hospital in excellent condition, the sciatica having disappeared. Supports, periodic rest and graduated exercises were prescribed and supervised, and a change of environment was advised.

She remained under observation for six weeks, during which time the functional insufficiency was relieved. She has been well for three years, without any recurrence of pain.

These three cases are typical of the sixty cases reviewed, both as to symptoms and observations and as to the response to treatment. Pain down the lower extremity was present in every case, the pain followed the course of a nerve, usually the sciatic distribution but occasionally a gluteal or lateral cutaneous distribution. Backache and a feeling of fatigue preceded and accompanied the sciatic pain; a localized pain was present usually either over the lumbosacral angle or over the sacro-iliac joint. The concomitant occurrence of static strain in the feet was frequently observed. Expressions of nervous strain such as irritability and insomnia were commonly present.

An explanation of the pathogenesis rests on an interpretation of the symptoms and observations. Osler states that sciatica may in some instances be a functional neurosis or neuralgia and that reflex irritation and an enfeebled nervous system may cause neuralgia. The ache in the back is a fatigue pain due to muscular insufficiency, the pain along the nerves is a referred pain. There were no objective signs that an organic lesion was present in any of these cases. The roentgenograms of the lumbar and sacro-iliac area were consistently normal. (Only such cases as presented negative roentgenograms were included in this series.) Osteoarthritis was carefully excluded. Many patients have an arthritis of the spine plus a muscle strain and sciatica. They may have a reflex sciatica as well as a true sciatic neuritis. Much of the back pain in arthritis of the spine is due to muscle spasm and secondary reflex neuralgia and only part of the pain is due to pressure on the nerve. The relief of muscular insufficiency gives distinct improvement in cases of arthritis of the spine with sciatica. Further arthritic treatment such as the careful elimination of foci of infection and the discriminate use of vaccines, is essential to establish a

cure. The latter is particularly true when the arthritic changes in the spine are part of a generalized or a chronic infectious arthritis. On the other hand, it is possible to have secondary arthritic changes limited to the lumbosacral and sacro-iliac joints as the result of continued irritation secondary to prolonged strain on these joints from muscular insufficiency of long standing. The cure of the muscular insufficiency in these cases assures permanent relief of all symptoms. The few instances in which the nerve came to the neuropathologist showed no sign of degeneration or inflammation, nor any abnormal change. In each case there was a definite relationship between the presence of static disturbance and the development of sciatic symptoms. Foci of infection, whenever present, were eradicated, since infection tends to increase the functional insufficiency and to make the irritation more persistent.

How can these static strains give rise to a reflex neuralgia? A reflex neuralgia occurs when a normal stimulus steps over the threshold of sensitivity to form an irritation. A persistent or repeated stimulus acts as a peripheral nerve irritant. Muscular fatigue or strain gives rise to such stimuli. The threshold of susceptibility of the nervous system may be lowered as a result of constitutional weakness or nervous fatigue. Thus all things that cause a strain, either physical or nervous, have a predisposing tendency toward a neuralgia. In many cases an injury or nervous shock precipitates a neuralgia. On the other hand, a mild stimulus repeated over a long period of time, as in the case of chronic muscular insufficiency of the back, gives rise to an accumulative effect, which finally expresses itself as a sciatic or some related form of neuralgia. All evidence indicates that sciatica is due to a disturbance in function. The muscle strains act as repeated stimuli and result in a peripheral irritation. These peripheral irritants give rise to reflex pain that radiates along the course of the peripheral sensory nerve. It is to these neuralgias or referred pains along the sciatic nerve that Goldthwait⁸ refers as some reflex mechanism. The explanation for relief from sciatica following a fusion of the sacro-iliac joint is simply that the procedure removes the sacro-iliac irritation and establishes a functional compensation.

These ideas are in accord with Linstedt's⁹ views that chronic irritations result from functional fatigue, that functional fatigue, in his cases, was secondary to organic alteration of normal body statics, that the irritation of chronic fatigue may make the nerve of the involved part hypersensitive and produce pain along the course of the nerve. When such pains occur in the region of the sciatic distribution they are called sciatica. These views were confirmed by Haglund's¹⁰ vast experience; he also found that the removal of functional insufficiency by means of orthopedic measures cured the sciatica. A detailed description of the treatment of muscular decompensation is not within the scope of this article. In the sixty cases reviewed, relief was obtained in each case as soon as a functional compensation was reestablished. These observations cover a period of seven years, during which time the patients have remained well.

METASTATIC SPINAL EPIDURAL
ABSCESSREPORT OF A CASE WITH RECOVERY FOLLOWING
OPERATIONR FRANK SLAUGHTER MD
FRANK FREMONT-SMITH, MD
AND
DONALD MUNRO, MD
BOSTON

This paper deals with a case of metastatic spinal epidural abscess due to an infection with *Staphylococcus aureus* in which the diagnosis was made and drainage provided before the appearance of signs or symptoms suggesting a compression of the spinal cord. We believe this case to be one of the first reported in which treatment has been instituted at such an early date, especially in the absence of meningitis. The outcome emphasizes the value of such a procedure.

Eleanor M., a well developed and nourished Italian school-girl aged 16 years admitted to the Second Medical Service at the Boston City Hospital, March 17, 1933 complained of pain in the lower part of the back which had been present for the preceding forty-six hours. It was stated that until the onset of her present illness she had been in perfect health with the exception of having had four subcutaneous abscesses during the previous year. The last one in the scapula had been healed for only ten days prior to her admission. Two days before admission at 10 p. m. she had suddenly felt a severe pain in the region of the lumbar spine. This had been accompanied by a chill and had radiated into both flanks. She slept that night and went to school in the morning, though the pain was still present. It grew progressively worse during the day and at 5 p. m. she went to bed feeling chilly and the next morning had a temperature of 101 F. She remained in bed that day, the pain becoming progressively more severe and the temperature rising to 102. She was brought to the hospital at 8 p. m. and transferred the following morning (March 18) to the neurologic service for special study.

At this time and at frequent intervals thereafter until she was operated on she was conscious and rational but slightly drowsy and complained of severe subjective and objective pain in the region of the upper part of the lumbar spine. On the scalp was the scar of a recently healed abscess of the right temporal region. There was a stiff neck and local tenderness over the twelfth thoracic and first lumbar vertebrae. The general physical examination was otherwise negative. Neurologic examination demonstrated a suspicious Kernig sign on the right and pain in the lumbodorsal spine with radiation to the flanks following forward flexion of the neck. Otherwise the motor and sensory systems and cranial nerves were entirely normal. The temperature remained below 101, and the pulse and respirations were normal. The urine was normal and roentgenograms of the spine were negative. Blood culture showed no growth and there was no anemia. On admission the white blood cell count was 19,000. This reached 20,000 the day before and 22,000 the day of operation. In the last count were 76 per cent of polymorphonuclear leukocytes.

Two lumbar punctures were done. The first on admission, showed an initial pressure of 170 mm of cerebrospinal fluid which fell to 50 mm following the removal of 5 cc of cerebrospinal fluid. There was a complete block, as evidenced by the failure of the lumbar cerebrospinal fluid pressure to rise following jugular compression. The collected fluid was clear and xanthochromic and had a slight clot. There were 200 leukocytes per cubic centimeter, 85 per cent of which were polymorphonuclear leukocytes. Ross-Jones and Pandey tests were strongly positive. The protein content was 420, the sugar 58 and the chloride 649 mg per hundred cubic centimeters. A smear showed no organisms. Because of the desire to rule

out tuberculous meningitis, one of the consultants suggested a second lumbar puncture. This was done the day of operation. The initial pressure was 320 mm of cerebrospinal fluid which fell to 0 after the removal of 10 cc. The spinal subarachnoid block was complete. The removed fluid was clear and xanthochromic and formed a solid clot almost at once. The cell count was 64 per cubic centimeter, all polymorphonuclear leukocytes. The protein was 770 the sugar 45 and the chloride 649 mg per hundred cubic centimeters. Coincidental serum sugar was 153 and serum chloride 575 mg per hundred cubic centimeters. The colloidal gold curve was 0000012333.

On this evidence the diagnosis of epidural abscess secondary to osteomyelitis of the twelfth thoracic and first lumbar vertebrae made by one of us (F. F.-S.) the day after admission was concurred in and the patient was transferred to the Neurosurgical Service and operated on, March 20, sixty-six hours following admission and five days after the onset of the disease.

At operation the laminae from the ninth dorsal through the second lumbar vertebrae were exposed through a midline vertical incision and after subperiosteal separation and lateral retraction of the muscles. The spinous processes were divided at their respective bases and instead of being removed were retracted to the right. The exposed laminae were then removed, a protruding soft mass of tissue being exposed at the level of the twelfth dorsal vertebra. This ruptured, exuding creamy pus followed the removal of the laminae of the eleventh dorsal vertebra. Cultures of this pus grew *Staphylococcus aureus*. After the exposure was completed it was evident that the epidural fat from the level of the ninth dorsal to the second lumbar vertebra was replaced by granulation tissue containing multiple small foci of pus. This infected tissue was removed with the aid of the "sucker" and a dural elevator, leaving the dura everywhere free and uninjured. A drain was inserted upward in the epidural space below the laminae of the eighth dorsal vertebra, and the wound closed loosely in layers around it.

Following the operation the patient's condition was satisfactory for two days. The third day, however, the temperature rose to 104. In addition she complained again of stiffness of the neck and pain in the back. All sutures were promptly removed from the wound down to the dura, the walls were picked widely apart with iodoform gauze and rubber dams and two hourly hot wet dressings were started. The temperature subsided the next day and the symptoms completely disappeared at the same time. In the course of a week the wet dressings were stopped, after which the pack was gradually decreased in amount and the wound allowed to heal from the bottom by granulation without further complications. She was discharged with a solidly healed wound and free of signs and symptoms May 10, less than two months from the date of admission.

LITERATURE

Acute spinal epidural infections, which should not be confused with the chronic granulomatous form,¹ are of two types. There are the metastatic or "primary" type, in which the vertebra is not involved, and the secondary type, which follows and results from osteomyelitis locally. The case reported herewith is of the metastatic or first type and the following discussion is therefore confined to this group. Pincoffs,² Craig and Doyle,³ Allen and Kahn,⁴ Chassierini,⁵ Mixer and Smithwick,⁶ Bellerose and Amyot,⁷ Klein⁸ and Rosa-

mond⁹ have all covered the literature and have reported cases of both types of acute spinal epidural infection. Twenty-nine of these were primary, of which the largest personal series is a group of six reported by Mixer and Smithwick. Of these twenty-nine patients, only six recovered. Recovery in each case followed operation. In one case reviewed by Dandy¹ the outcome is not stated. The other twenty-two patients died. Of the six that recovered, two had residual paralysis of the lower extremities. All operations followed the onset of meningitis or cord compression, as evidenced by paralysis or anesthesia of the lower extremities or interference with the bladder function.

DIAGNOSIS

In the presence of the complete syndrome the diagnosis of acute, metastatic epidural spinal abscess should not be difficult, provided it is considered as a possibility. There will be evidence of the source of the infectious metastasis by the presence of either recently healed or active staphylococcal infection elsewhere in the body. Localized pain and tenderness with muscle spasm as evidenced by stiffness of the neck as well as the aggravation of the symptoms following forced flexion of the cervical spine will be suggestive. General symptoms of an acute inflammatory disease, such as malaise, fever and leukocytosis, will serve to confirm one's opinion. Finally, the demonstration of the signs and symptoms of compression of the spinal cord with or without meningitis will make the diagnosis extremely probable.

The final determining factor, however, and the one which, if successfully demonstrated, indicates the treatment to be followed, is the determination of the presence of a spinal subarachnoid block. This may be present for several days before the clinical signs of compression of the cord are manifest and will almost certainly antedate the onset of meningitis. It may be demonstrated either by chemical changes in the cerebrospinal fluid below the level of the block or by interference with the transmission of a pressure wave from the ventricles down the spinal subarachnoid space and into a manometer. Lumbar puncture was performed in fifteen of the twenty-nine cases reported in the literature. In seven of these sufficient information was given so that it is apparent that a block was present. Six of these seven presented a yellow fluid which clotted with a pleocytosis in one and normal cell count in three. Such observations are pathognomonic of subarachnoid block at a level higher than the insertion of the needle. In the earliest stages, however, the cerebrospinal fluid may be normal and the demonstration of the block must depend on mechanical rather than chemical means. One patient was subjected to two punctures with an interval between. In this instance Craig and Doyle³ found a normal fluid without block six days after the onset of the symptoms. Nine days later, after paralysis had set in, a complete block with yellow cerebrospinal fluid which clotted, was demonstrated. This patient recovered following operation. Our patient showed complete block with yellow fluid and pleocytosis at both examinations. She also recovered following operation.

Such data can be determined with certainty only with the aid of a lumbar puncture. Under the circumstances, however, as Mixer and Smithwick have emphasized this procedure is fraught with particular danger.

To reach the subarachnoid space it is necessary to cross a possibly infected epidural space. If the latter region is actually infected, the needle becomes contaminated and mechanically deposits bacteria into the previously sterile subarachnoid cavity. That this may result in meningitis is only too obvious. Death or permanent disability does not necessarily follow, however. Rosamond⁹ and Mixer and Smithwick⁶ each report a case in which recovery followed the development of such a complication, while Pincoffs² obtained pus from the epidural space in one case, inserted the needle still farther and withdrew cerebrospinal fluid and found that the infection was strictly limited to its original site at subsequent observation. On the other hand, to delay laminectomy, through failure to do an early lumbar puncture, until classic signs of cord compression have manifested themselves in itself greatly increases the chances of a complete recovery, with the elimination of residual paralyses of the cord and bladder. We feel that the danger from a properly performed lumbar puncture is no greater than that that accrues from delay in making the diagnosis and that fear of causing a meningitis which would not otherwise develop should not prevent the operator from obtaining these essential diagnostic data, which can be obtained in no other way. If the diagnosis is suspected, aspiration should be made on the needle at intervals during the puncture and particularly after the interspinous ligament has been traversed. If pus is obtained before the subarachnoid space has been entered, the needle should be promptly withdrawn and operative drainage instituted at the earliest possible moment. We believe that the value of this point of view is well illustrated by the case reported herewith.

TREATMENT

Once the diagnosis is made, only one type of treatment is permissible. This must conform to the fundamental requirement of complete and adequate drainage of the abscess. This is not as simple as it sounds, for the abscess cavity in these cases may include the entire spinal epidural space. In any event, a laminectomy centered over the point of greatest tenderness should be performed. The epidural fat will be found to be studded with multiple small collections of pus, and laminae should be removed in both directions sufficiently far to uncover the maximum amount of this infected tissue and at the same time produce only a reasonable amount of weakening to the spinal column. If the extent of the infection is too great to permit of its complete exposure, drains should be inserted upward and downward in the epidural space. In addition, the dura should be left unopened and as clean as it is possible to get it. It is of even greater importance, however, to leave the operative wound completely unsutured. Recovery followed in our case only when inadequate partial drainage of the abscess through a "loosely sutured wound" was changed to adequate drainage through a wound packed widely open. If gauze is used to pack the wound open it must be replaced every day and in the interval kept wet by the application of large very wet sterile dressings. The wound must be made to granulate from the bottom and great care must be exercised to prevent pocketing particularly at the ends. The necessity for postoperative support of the back will depend entirely on how many laminae have been removed.

SUMMARY

Acute spinal epidural abscess is a definite clinical entity that can be recognized before the onset of com-

⁹ Rosamond E. Epidural Abscess Complicated by Staphylococcal Meningitis. Report of Case with Complete Recovery Following Operation. *J. Pediatr.* 1: 210 (Aug.) 1932.

pression of the spinal cord. The diagnosis must be confirmed by the demonstration of a subarachnoid block by means of a lumbar puncture. The mortality from meningitis brought on by this procedure is certainly no greater and may well be less than the inherent mortality of the disease plus the mortality that results from delayed treatment.

The onset of the disease is characterized by the occurrence of a sudden severe pain in the back, which tends to radiate into nerve root fields. There is a varying degree of systemic toxemia such as accompanies any undrained major infection of soft tissues. A history of either a recent healed or an active unhealed staphylococcal infection is confirmatory evidence. The diagnosis is established and treatment indicated following the demonstration of pus in the epidural space or spinal subarachnoid block. These data can be ascertained only by a properly performed lumbar puncture together with an adequate chemical examination of the cerebrospinal fluid. Signs of meningitis and paralysis resulting from unrecognized cord compression or destruction are late manifestations, and their presence is not essential to the diagnosis.

Treatment is surgical. It should provide complete and adequate drainage of the abscess if at all possible. The operative wound should be left completely open and without sutures.

A case in which complete recovery followed early and adequate drainage of the spinal epidural space illustrates these points.

PORTAL CIRRHOSIS IN A CHILD, WITH SUCCESSFUL PALLIATION BY OMENTOPEXY FOR TWO YEARS

MARTIN NORDLAND, M.D. AND LAWRENCE M. LARSON, M.D.
MINNEAPOLIS

The usual conception of cirrhosis of the liver denotes any type of sclerosis in which there is destruction of liver cells associated with a real or apparent increase of connective tissue. The terms "atrophic" and "hypertrophic" referring to the size of the liver should be abandoned, since they do not indicate any definite disease entity but more a description of the stage of the disease. Early in the hypertrophic stages of the disease exudation and necrosis of liver cells are the prominent features and replacement by the healing process is yet in the background. Later, when a large proportion of the necrotic liver cells have become replaced by scar tissue through a process of healing, the liver is decreased in size, this is usually designated as "atrophic" cirrhosis.

Any type of cirrhosis of the liver in childhood is a rare disease, but the portal or Laennec type is especially uncommon as judged from the report by Bridgeman and Robertson¹ of only fourteen such cases which they were able to collect from the literature. They noted a definite familial tendency in the cases of this type which they reviewed. Considering all types of hepatic cirrhosis in the literature, they found most commonly the multilobular alcoholic, the biliary obstructive and the syphilitic varieties, with the latter two types predominant.

The case described here is reported not alone from the standpoint of its rarity but, in addition to emphasize and recommend a form of treatment that was successful in bringing about complete symptomatic relief. Although this therapy probably did not alter the eventual outcome of the disease, the patient enjoyed two years of normal health, in addition, many interest-

ing and difficult diagnostic features were encountered in this case, so that it seems worthy of report.

REPORT OF CASE

A white girl, aged 6 years, was first admitted to the hospital, Nov. 17, 1931, with complaints of painless, gradually deepening jaundice, acholic stools, dark urine, and slight loss of weight and weakness for the past four or five months. The onset of her illness was very insidious and the progression of her symptoms was very slow. There had been at no time any fever, chills or abdominal pain, although she had occasional periods of a few days in which the stools were normal in color. Her past history as well as that of her family was entirely negative for any tendencies.

The child was rather well developed and well nourished. Jaundice was graded 3 plus on a basis of 4. The tonsils had been removed previously but otherwise no abnormalities of the head, neck or chest were found. The liver was palpable 4 cm. below the costal margin and its margins were smooth but tender. The spleen was slightly enlarged and its anterior margin could be barely palpated on deep inspiration.

Examination of the blood showed a hemoglobin concentration of 78 per cent by the Darc method. The red cells numbered 4.2 million and the white cells 13,375 per cubic millimeter of blood. The urine contained sugar graded 3 plus on the basis of 4 and also a faint trace of albumin but no acetone or pus. A negative serologic reaction on the blood was obtained for syphilis. The van den Bergh test gave both the direct and indirect reactions and the value for the serum bilirubin was estimated to be 10.2 mg. for each hundred cubic centimeters of blood. The coagulation time of the blood was found to be seven minutes and thirty seconds. Blood sugar determinations varied between 62 and 104 mg. for each hundred cubic centimeters of blood.

Since the possibility of an obstructing lesion of the common duct could not be excluded, it was decided that exploratory laparotomy was advisable. Preoperatively, 20 cc. of 10 per cent calcium gluconate was given by vein, as well as large amounts of fluid and dextrose parenterally. At operation the liver was found to be almost twice its normal size, with many irregular hard nodules involving especially the left lobe, the largest of which were about 3 cm. in diameter. The gallbladder was markedly distended, seemingly from the obstruction caused by the presence of a number of enlarged lymph nodes surrounding and compressing both the common and cystic ducts. Ascites measuring a liter or more was present in the abdominal cavity. Removal of a small section of hepatic tissue and of a nearby gland for biopsy was done, and pathologic report by the frozen section method was immediately returned as a marked cirrhosis of the Laennec type, and chronic inflammation of the lymph node. The mass of glands about the bile ducts was removed as extensively as possible and a Talma Morrison omentopexy was then done. Convalescence was essentially without incident. In about two weeks the jaundice had completely disappeared, and the child began to gain weight and strength and soon appeared to be entirely normal in every respect. She went to school, was always very active, and for almost two years there were no symptoms whatever referable to her previous trouble. In October 1933 a few days after a fairly severe "take" from a smallpox vaccination, she again became jaundiced, her abdomen became distended and in spite of a strict limitation of diet, the symptoms progressed. A week later the child rather suddenly became comatose and died in twenty-four hours. A van den Bergh test taken just before death gave both a direct and an indirect reaction and the serum bilirubin value of the blood was 19.9 mg. for each hundred cubic centimeters.

At necropsy the body appeared well developed and nourished, measuring 130 cm. in length and weighing about 100 pounds (45.4 Kg.). There was deep generalized jaundice. The peritoneal cavity contained about 200 cc. of bile-stained ascitic fluid. The omentum was extensively attached to the anterior surface of the liver, and to the parietal peritoneum over almost the entire anterior abdominal wall. The spleen weighed 260 Gm. and its content of fibrous tissue was only slightly increased over that of the normal. The weight of the liver was 520 Gm. Its surface was rough and nodular, owing to the presence of many adenomas varying in size up to 4 cm. in diameter. The

¹ Bridgeman, M. L. and Robertson, T. D. Familial Juvenile Cirrhosis of the Liver. *Am. J. Dis. Child.* 43: 1155 (May) 1932.

liver on section was very firm and in its substance practically nothing but scar tissue could be made out, although islands of hepatic parenchyma were visible, the latter no doubt represented the remnants of preexisting lobules. These nodules were much more prominent in the left lobe than the right.

The gallbladder was thin walled and slightly distended with light colored bile. The ducts of the biliary tract were normal and patent throughout. Examination of the remainder of the gastro intestinal tract and also of the organs of the genito-urinary and the cardiorespiratory systems gave negative results.

Microscopically, there was considerable hypertrophy and hyperplasia of the liver cells, which was no doubt the source of regeneration of hepatic tissue. The liver stroma was contracted by a large increase of connective tissue, compressing the sinusoids and periportal biliary ducts. There were numerous lymphocytic collections in the periportal connective tissue, completing the picture of a typical portal cirrhosis.

COMMENT

Perusal of the available literature gave unsuccessful results in finding a description of a similar case. In adults, comparable situations have been frequently described, in children, treatment of this disease in the manner indicated apparently is of great rarity. Decompression of the portal hypertension by shunting blood from this system over to the systemic circulation afforded relief from the ascites, jaundice and glycosuria led to a decrease in evidences of collateral circulation, and brought about symptomatic cure for almost two years. A rapidly fatal issue finally occurred from almost total hepatic insufficiency a mode of death frequently seen in this disease.² There is doubt as to the role played by the reaction to vaccination in the precipitation of the fatal issue, from the degree of liver damage present there is no question that death was imminent at any time and the smallest disturbance in the physiologic equilibrium would have resulted fatally. From observations in this case it would seem that omentopexy is of as much value in the treatment of portal obstruction in children as it is in adults.

BARIUM CHLORIDE POISONING

CLARENCE F. GRAHAM, M.D., ALBANY, N. Y.

A recent query in THE JOURNAL as to the toxicity of barium carbonate¹ prompts the report of a case of poisoning by barium chloride in an amount well beyond the commonly fatal dose.

A woman, aged 25, a stenographer in a chemical laboratory, asked one of the chemists for a teaspoonful of salt to relieve slight gastric distress. The chemist took a bottle out of the chemical cabinet under the impression that it contained sodium chloride and, glancing only at the "ium chloride" of the label gave her about a teaspoonful of barium chloride which she immediately washed down with a glass of water.

The peculiar taste caused the error to be discovered at once but as the young woman felt no immediate ill effects nothing was done at the time. After a few minutes she began to have some gastric pain which increased to such a degree that she took a little sodium bicarbonate for relief. As this did no good she went home an hour after taking the barium salt and was almost prostrated by abdominal pain. About two and a half hours after the accident she was given 2 teaspoonfuls of anhydrous sodium sulphate by the chemist and I was called.

When she was seen about three hours after the ingestion of the salt she was almost in collapse with a weak thready pulse of a rate of 120 and complained of agonizing abdominal pain crampy in character and general over the whole abdomen. There was no abdominal rigidity and pressure did not increase the pain to any extent. The systolic blood pressure was 140. Without further examination 4 teaspoonfuls of crystalline sodium sulphate was at once given in water followed by a hypodermic injection of $\frac{1}{100}$ grain (0.00065 Gm.) of atropine sulphate and $\frac{1}{4}$ grain (0.016 Gm.) of morphine sulphate. The pain was relieved at once and the next day the patient felt as well as usual.

² Chapman, C. B., Snell, A. M., and Rowntree, L. G., Decompensated Portal Cirrhosis. Report of One Hundred and Twelve Cases. *J. A. M. A.* 97: 237-244 (July 25) 1931.
¹ Poisoning with Barium Carbonate. Queries and Mirror Note. *J. A. M. A.* 101: 625 (Aug. 19) 1933.

Later the patient was asked to measure out in a teaspoon the amount of barium chloride she had swallowed, and the weight of the quantity she indicated was found to be 7 Gm., or about 108 grains. Reference to textbooks of pharmacology shows that much smaller doses have been fatal. Witthaus² states that death has been reported from 4 Gm. of barium chloride, while recovery has occurred after the ingestion of 24 Gm. Sollmann³ refers to the fatal dose as from 0.8 to 0.9 Gm. Barium chloride is now rarely used in medicine and is not mentioned in the twenty-first edition of the Dispensatory of the United States. The National Dispensatory of 1916 gives the dose as from $\frac{1}{10}$ to $\frac{1}{2}$ grain (0.0065 to 0.032 Gm.), while Merck's Index for 1907 indicates a dose of from $\frac{1}{2}$ to $1\frac{1}{2}$ grains (0.032 to 0.096 Gm.), with a maximum single dose of 3 grains (0.194 Gm.) and a total daily dose of 10 grains (0.648 Gm.).

Sodium sulphate reacts with barium chloride according to the equation $\text{BaCl}_2 + \text{Na}_2\text{SO}_4 \rightarrow \text{BaSO}_4 + 2\text{NaCl}$. In this reaction sodium sulphate is a perfect chemical antidote for the barium chloride. It is readily soluble in water, it can be given in a dose as large as 30 Gm., and the end-products are non-toxic. Ordinary barium chloride contains two molecules of water of crystallization, and crystalline sodium sulphate ten molecules, so that 1 Gm. of barium chloride is fully converted into the insoluble sulphate by 1.31 Gm. of sodium sulphate in crystal form.

Sodium thiosulphate, commonly used as an antidote to the heavy metal poisons precipitates barium thiosulphate from a solution of barium chloride. The barium, however, is not completely thrown down even by a saturated solution of the thiosulphate, and the addition of sodium sulphate causes a further precipitation. Sodium sulphate, therefore, is a more efficient antidote to barium chloride than sodium thiosulphate.

THE PREPARATION OF BACILLUS PERTUSSIS VACCINE FOR IMMUNIZATION

LOUIS W. SAUER, M.D., EVANSTON, ILL.

For immunization against whooping cough to be free from unnecessary hazards the recently isolated strains of Bordet-Gengou bacilli should be grown only on Bordet medium, made with 20 per cent fresh, defibrinated human blood. A total of from 7 to 8 cc. of such vaccine containing 10,000 million bacilli, is necessary to confer prolonged immunity.¹ Because the amount of culture medium blood protein that is unavoidably carried over when the forty-eight hour growth is harvested is not negligible, the growth is scraped off. To flood off the harvest would carry over appreciably more, at times sufficient to give the product a pink tinge. To rid the vaccine of such transferred blood protein by washing, centrifugation and replacement of the supernatant fluid would weaken, i. e., decrease the antigenic content of the vaccine. I have found the original supernatant fluid to contain an appreciable amount of soluble toxin.

The use of animal (horse, sheep or goat) blood would add an unnecessary hazard when such quantities of vaccine are administered. Clinicians are familiar with the systemic and cutaneous reactions that promptly follow the use of antitoxin (tetanus or scarlet fever) in children who have previously been immunized against diphtheria with toxin antitoxin. Because the trace of animal serum in the latter sensitizes the young child to oxoid or alum toxoid is rapidly replacing toxin-antitoxin as an immunizing agent. To avoid similar sensitization only vaccine made with human blood should be used in the immunization of infants and young children against whooping cough.

Furthermore from accumulated evidence I have cause to believe that medium made with human blood is most likely to conserve the pathogenic (Leslie and Gardner's phase I) phase of the bacillus.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
II A CARTER Secretary

ARIZON ACCEPTABLE

The Arizon is an electrically heated vapor inhalator manufactured by the Detroit Cover Company, 3420 West Fort Street, Detroit. It is recommended as an adjunct in the treatment of nasal or respiratory disturbances and for inhalations of vapor or medicated vapor as prescribed by the physician. The unit weighs about 4 pounds and operates on either alternating or direct current with electric consumption of about 150 watts. A tight mask with compensating valves fits over the nose and mouth. A flexible breathing tube serves as a connection between the mask and the vapor chamber.

Arizon Respirator

Ventilators are drilled in the base of the instrument so that the free ingress of air is available for inspiration. An outlet valve in the mask provides for expiration and the arrangement of valves prevents expired air from being inhaled again. The intake of air, after passing through the ventilators is drawn through and over an electric heating element thence passing into a spherical vapor chamber measuring seven inches in diameter. Wiring of the instrument provides for three heat stages in the basin of the Arizon. Sufficient hot water is placed in the basin to provide adequate vapor. The treatment consists simply of normal breathing. If the Arizon is to be used by several people, one after the other, for example in a family, the mask and the breathing tube should be thoroughly sterilized in boiling water for fifteen minutes. The unit should not be passed around in a community from one family to another. One unit was examined in a clinic acceptable to the Council. It was found to be a satisfactory means of conveying vapor either medicated or not to the patient. The Arizon therefore, is eligible for inclusion in the list of acceptable devices.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

COMMANDER FANCY SHORT PATENT FLOUR
FAIRYLITE FANCY PATENT FLOUR
MISS MINNEAPOLIS FANCY SHORT PATENT FLOUR

The Commander Milling Company, Minneapolis and its subsidiaries the Buffalo Flour Mills Corporation, Buffalo and the Minneapolis Milling Company Minneapolis respectively submitted to the Committee on Foods the following hard spring wheat patent flours intended for commercial bakeries and family use Commander Fancy Short Patent Flour, Fairylite Fancy Patent Flour and Miss Minneapolis Fancy Short Patent Flour.

Analysis (submitted by manufacturer) —

Moisture
Ash
Protein (N × 5.7)

per cent
13.0 - 14.5
0.38 - 0.42
10.5 - 12.0

Discussion of Names—The designations fancy patent and 'fancy short patent' are not recognized by the milling trade or by the public as defining any specific flour grade. The term fancy implies at least that the flour grades are superior to those generally recognized as 'patent' or 'short patent'. The submitted information would classify the flours as 'patent' only. Variety of grade names without recognized significance

COMMITTEE ON FOODS

JOUR. A. M. A.
MAY 5 1934

for flours leads to confusion and deceptive advertising. There fore the grade names 'fancy patent' and 'fancy short patent' are considered inappropriate, first, because the names do not have trade recognition and secondly, because they connote that the flours are lower percentage patents than reported and consequently have superior baking values. The company was advised of the Committee's recommendations but is unwilling to change the names for business reasons. Acceptance of flours with inappropriate grade designations would militate for their more general adoption and extend this misinformative practice. These products will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.
RAYMOND HERTWIG Secretary

HEINZ STRAINED PRUNES WITH LEMON JUICE

Manufacturer—H. J. Heinz Company, Pittsburgh
Description—Strained prunes retaining in high degree their natural vitamin and mineral content, added lemon juice.
Manufacture—Dried prunes are inspected, washed, cooked in boiling water in closed kettles, and automatically pitted. The pulp with sufficient fresh lemon juice to add 0.5 per cent of citric acid, is sieved in an atmosphere of steam vacuumized to remove air filled into lacquer lined cans, sealed under vacuum and processed.

JELKE'S GOOD LUCK SALAD DRESSING

Manufacturer—John F. Jelke Company, Chicago
Description—Salad dressing containing water cottonseed oil, sucrose, distilled vinegar, starch eggs salt and mustard.
Manufacture—The eggs, spices and a small amount of the distilled vinegar and water are mixed at a slow speed, the oil is beaten in at high speed and then the balance of the distilled vinegar and water. The resulting emulsion is mixed with a heated mixture of water sugar, distilled vinegar, starch and salt producing the salad dressing which is cooled and automatically packed in jars.

REPORTS OF OFFICERS

NOTE—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion—Ed

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association

The following report of the Secretary is respectfully submitted

MEMBERSHIP

On April 1, 1934, the number of members enrolled was 98,041. The names of 1,537 deceased members were removed during the year. Because of a typographical error in the report submitted at the last Annual Session the number of members as of April 1, 1933, was incorrectly stated. The number reported for Missouri should have been 3,212 and the total 98,111, rather than 2,212 and 97,111, respectively.

FELLOWSHIP

The number of Fellows as shown by the roster on April 1, 1934, was 60,714, as compared with 62,495 on the same date in the preceding year. During the year 5,563 names were removed from the roster, while 3,782 were added. The net loss for the year was 1,781. Of those removed the names of 789 were those of deceased Fellows. 1,202 had become ineligible for various reasons, 1,903 had failed to pay dues, 1,669 resigned. In most instances resignations were based on expressed desire to be relieved of the payment of Fellowship dues and subscription because of the unfavorable economic situation. A few resignations were submitted with statements indicating dissatisfaction with existing conditions in component and constituent societies or disapproval of the announced policies of the Association. A slightly larger number of resignations were submitted without any accompanying statements of the reasons therefor.

In accordance with instructions issued by the Board of Trustees and approved by the House of Delegates at the Milwaukee session, the names of Fellows who could not make immediate remittance for Fellowship dues have been retained on the roster when they have indicated intention to remit within a specified time.

The number of counties in each state and territory, the number of component county societies as shown by the records of the Secretary's office, the number of members enrolled at the time the count was made, and the number of Fellows including Honorary Fellows and commissioned officers of government services, are shown in an accompanying table.

FIELD WORK

The Secretary has attended meetings of state associations and district medical societies in twelve states during the year and has appeared before eight county societies. He has also attended meetings of councils and other official bodies in several states and has accompanied committees of the Association on official visits to Washington and elsewhere. The number of official visits made by other representatives of the Association to the meetings of state, district and county medical societies and the number of appearances of such representatives before lay audiences have been far larger than in any previous year.

REAPPORTIONMENT OF DELEGATES

Under the provisions of section 3, chapter 1 of the By-Laws it is required that a reapportionment of delegates shall be made every third year. The last reapportionment was made at the Philadelphia session in 1931 and it will therefore be necessary to make a new reapportionment at this session.

COUNTY SOCIETIES

The need for efficient and militant organization in the individual counties has been demonstrated in truly remarkable

manner during the last year. It has been clearly shown in numerous instances that where such organization has been lacking the medical profession has been placed at serious disadvantage. It has been just as clearly demonstrated that well

organized and viable county societies have many times been able to stem adverse tides and to render valiant service for medicine and for the people of their own communities.

Several entirely new county societies have been organized during the year. Colorado having taken the lead as we are informed with three. There is a continuing tendency to the organization of the province of two or more counties in a single component society.

STATE ASSOCIATIONS

There has been a marked increase in the efficiency and in the scope of the activities of most of the constituent state associations

RESOLUTION TO BE SUBMITTED BY DELEGATES OF
THE MICHIGAN STATE MEDICAL SOCIETY

WHEREAS There is substantial evidence that powerful forces and agencies are working toward the development of health insurance in the United States and

WHEREAS During the course of its studies of medical economic problems the Michigan State Medical Society after a conference with officials of the American Medical Association found it necessary to send a commission to England to inquire into the subject of health insurance and

WHEREAS The commission presented the following report
[This report is not reproduced because of its length. The Secretary is informed that it appears in full in the *Journal of the Michigan State Medical Society* May 1934] and

WHEREAS The report of the commission raises certain grave questions concerning the policy of the officials of the American Medical Association toward health insurance and the effects of this policy on the practicing membership of the American Medical Association and

WHEREAS The report of the commission was transmitted to the Board of Trustees of the American Medical Association through the chairman in February 1934 and

WHEREAS The Michigan State Medical Society has received no word nor has it any other evidence that the Board of Trustees of the American Medical Association has considered or acted on the report transmitted in February 1934 therefore be it

Resolved That in order to avert a repetition in the United States of the disastrous consequences that attended the adoption of health insurance in England the Speaker of the House of Delegates of the American Medical Association appoint a committee to investigate and consider the policy of the Association toward health insurance and present a report to the House of Delegates

To the secretaries and other officers of county societies and state associations to the officers and members of official bodies of the American Medical Association to members of this House of Delegates and to many others from whom assistance has been received including his office assistants, a most sincere expression of grateful appreciation is hereby offered by the Secretary

Respectfully submitted

OLIN WIST, Secretary

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association

The hours of work in the various departments of the Association have been curtailed and the requirements of the law with respect to wages have been strictly met in compliance with the provisions of the National Recovery Act and with the rulings of the National Recovery Administration promulgated under that act, and with the desire to cooperate as fully as possible with the President and other official agencies of the federal government. The reduction of the number of working hours has, naturally, created a necessity for adding to the working personnel in some departments and has increased the labors of a very considerable number of the employees of the Association.

An examination of that part of the Auditors' Report dealing with the general operating expenses will show that practically all operating costs were less in 1933. Expenditures for wages and salaries paid in 1933 were less than in the preceding year by the sum of \$39,211.85. Expenses incurred in carrying on the general activities of the Association, including field work and the operation of various bureaus and councils were less during the year covered by this report than in the preceding year by approximately \$10,000, while the total expenditures of a miscellaneous nature were less by a sum slightly in excess of \$55,000.

The total operating income for the year 1933 was \$1,375,337.99, as compared with \$1,534,609.98 in the preceding year. There was a decrease in the amount of income received from rents and sundry publications of approximately \$11,000. Interest received from investments amounted to \$77,402.83, as compared with \$74,967.03.

The net income for the year covered by this report was \$88,465.04, as compared with \$93,842.75 in the year 1932. Of the entire net income, \$77,402.83 was derived through interest paid on investments, while the sum of \$5,929.38 represented miscellaneous income secured through several minor sources. The actual net operating income, therefore, amounted to slightly more than \$5,000.

There were very significant decreases in the amount of various cost items, including wages and salaries, paper, postage, discounts and factory supplies, while the increases in operating expenses applied only to a few minor items.

The value of real estate owned by the Association was written down to the extent of \$40,000. It is possible that this represents a somewhat ultraconservative figure, since it is undoubtedly true that on the basis of present conditions in the real estate market the depreciation of the Association's holdings may be considerably larger. The Board of Trustees, in fixing the amount of depreciation on real estate as shown in the Auditors' Report, felt that it was best to adopt a conservative attitude about the matter and to avoid the necessity of presenting figures in a later report which might be construed as showing undue appreciation in value.

Recently, it has become necessary to employ additional personnel in several departments because of constantly increasing demands and because of curtailment of office hours required by the National Recovery Act. If pending legislation is enacted into law, working hours will be further shortened, and it will then be necessary to employ additional personnel. Since it is contemplated, under the proposed law, that present salary and wage scales shall be maintained even though working hours are shortened, it is apparent that expenditures required for the payment of salaries and wages during the current year will be considerably increased.

The cost of paper and various other commodities is now considerably higher, and this fact will be reflected in the operating costs in 1934.

The Journal

In addition to publishing the usual scientific material and the well established special issues during 1933, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION devoted particular attention to the question of medical economics. The subject was covered not only in the department devoted to the Bureau of Medical Economics but also in editorials, news items and special articles.

The high standards of THE JOURNAL in the field of medical science have been constantly maintained, and the response of the profession has been sustained as in previous years. THE JOURNAL has been devoted to the interest of the medical profession and to its policies as set forth by the House of Delegates and the Board of Trustees of the American Medical Association.

More and more the value of THE JOURNAL as a spokesman for American medicine is being recognized by the medical profession, by government officials and by organizations representing other professions. These have sought constantly the cooperation of THE JOURNAL in representing the medical profession and in promoting various official matters.

The most significant aspect of the work of THE JOURNAL during 1933 has been the continued development of the department of Queries and Minor Notes. A great many letters have been received in the headquarters office testifying to the appreciation of physicians for the practical and clinical service rendered in this way. Hundreds of competent authorities throughout the country have cooperated in preparing the replies, and the appreciation of the Board of Trustees is tendered to them for their work.

The approximate count of Fellows and subscribers carried on the mailing list of THE JOURNAL is shown by states in table 1, in which the gain or loss of Fellows and subscribers in each state is indicated.

A second table shows the number of physicians receiving THE JOURNAL in each state.

The total number of copies of THE JOURNAL printed in 1933 was 4,427,974, while the average number of copies printed weekly was 85,153. There was a decrease of 3,412 in the number of subscribers in 1933 as compared with the preceding year.

The Special Journals

The periodicals devoted to the specialties which are published by the American Medical Association are recognized throughout the world as leaders in their fields. The high standards set in previous years have been constantly maintained during 1933, notwithstanding the fact that the economic depression raised costs of publication and lowered somewhat the total numbers of subscriptions. Nevertheless, the interest manifested has been more than sufficient to indicate the manner in which the groups concerned depend on these periodicals for their scientific pubalium.

The boards of editors have labored assiduously in their attempts to select only material of the highest quality and to eliminate unnecessary illustrations, charts and tabular matter, which add greatly to the costs of publication.

Again the Board of Trustees wishes to tender its appreciation to various research institutions and to various individual physi-

TABLE 1—Approximate Count of Fellows and Subscribers on The Journal Mailing List Jan 1, 1934, Also Gains or Loss During 1933

ciens who have aided the publication of special articles in these periodicals by bearing portions of the costs of publication.

The special periodicals are of great importance in the advancement of medical science. It is significant that no other medical organization in the world has been able to perform a comparable task in so efficient a manner.

Three of this group of journals produced incomes larger than the costs of publication—the ARCHIVES OF OTOLARYNGOLOGY

the ARCHIVES OF OPHTHALMOLOGY and the AMERICAN JOURNAL OF DISEASES OF CHILDREN.

The total circulation of all the special journals, Dec 31 1933 was 19,346. The costs of publication exceeded income by the sum of \$10,471.56. This represents a very considerable decrease as compared with the loss sustained in the preceding year.

The Quarterly Cumulative Index Medicus

This monumental contribution to medical bibliography is one of the works of the Association in which the Board of Trustees takes great pride. All of the editorial preparation for this

This table gives the number of physicians (based on the Twelfth Edition of the American Medical Directory) in the United States, the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army and Navy are not included.

periodical is now carried on in the library of the American Medical Association. The adaptation of the work of the Association to the new federal code made it necessary to add additional personnel in this department.

The total number of periodicals now regularly indexed approximately 1,200. These publications represent all the important medical literature of the world but do not include health bulletins, small hospital bulletins, bulletins of county medical societies or similar publications. The development of an index in the field of veterinary medicine and in the field of social and biologic science enables the QUARTERLY CUMULATIVE INDEX MEDICUS to diminish somewhat its efforts in these departments which bear a definite relationship to medical science.

The medical librarians of the United States met in Chicago in their annual session and were unanimous in their praise of this undertaking. The total subscription does not begin to indicate the usefulness of the index. In libraries throughout the country it is almost constantly in use by medical students, physicians and research investigators.

The number of copies of the *QUARTERLY CUMULATIVE INDEX MEDICUS* distributed in 1933 was 1,932, as compared with 2,048 in 1932. The loss incurred in publication of the index was \$44,759.78.

Hygeia

Notwithstanding the severe financial depression, extraordinary efforts by the circulation department of *HYGEIA* maintained its circulation list during 1933. However, the expenditure necessary for this purpose obliterated the usual small profit yielded by this publication during the past decade, so that for the first time in some years it presented a financial loss. Nevertheless, the large advance payments of subscriptions for the future indicate that the periodical should return to the profit side as soon as financial conditions are stabilized.

Today *HYGEIA* reaches hundreds of schools, many great industries, public and medical libraries and a large number of individuals who are interested in receiving sound material in the field of medicine and public health. It has been a source from which many other smaller publications, such as the bulletins of hospitals, sanatoriums, schools and other institutions, have drawn. In numerous educational institutions, *HYGEIA* has formed the projects for study by young people, who are now getting a type of education in health in their adolescent years not available in a previous generation.

Typographically, *HYGEIA* has been maintained at an exceedingly high level, and numerous letters of commendation have been received from readers commenting on the attractiveness of the publication.

A series of articles on the care of the eyes, one on plastic surgery, and especially an extended series on the subject of education in sex have been highly endorsed by hundreds of leaders and have indicated again the many phases of application of a publication of this kind to the welfare of mankind.

Both the subscription and the advertising income were seriously affected by the unfavorably economic situation, so that for the first time in several years the costs involved in the publication of *HYGEIA* were larger than income received. The total loss recorded for the year amounted to \$30,127.54. It was only through the practice of rigid economies that a much larger loss was averted. It is extremely gratifying to report to the House of Delegates that there has been a considerable increase in circulation during the early months of the current year. It is hoped that through intensive and persistent effort and with the cooperation of the members of the Association and of other agencies, the circulation of *HYGEIA* will be greatly extended.

While *HYGEIA* is published for the purpose of providing information to the public from authentic sources, it is entirely reasonable to expect that it will receive the cordial support of the medical profession through subscription. The fact is, however, that only 14,296 physicians in the United States subscribed to *HYGEIA* during the year 1933.

The Library

The package library service furnished by the American Medical Association is now recognized among physicians as one of the most practical and useful services offered by the headquarters office. The physicians who have availed themselves of these packages have written by hundreds to commend the quality of the material received and the manner of the service.

In comparison with similar services rendered by other organizations both mutual and commercial, the standards are exceedingly high. Especially commended has been the promptness with which the service is rendered and the diversity of the material included.

During 1933, 2,325 physicians availed themselves of these packages. It is testimony to their appreciation of the service that only two packages were lost during the year and that the vast majority of the physicians who used the service complied fully with the rules regulating the service. A tabulation of the requests indicates that physicians in smaller communities who do not have other access to competent medical library service are especially appreciative of this work of the American Medical Association.

The gradual development of similar medical package library services by state medical societies and by other organizations

indicates that the Association has here pioneered in a field of the greatest importance.

The periodical lending service, which supplements the package library service, sent out 6,903 periodicals to physicians in response to individual requests during 1933. All the periodicals regularly listed and abstracted in *THE JOURNAL* and all those regularly received by the *QUARTERLY CUMULATIVE INDEX MEDICUS* are available for such loans.

The library of the Association also supplied bibliographic material in response to approximately 5,000 individual requests made during 1933. The circulating library maintained for employees issued over 6,330 books, or a daily average of 23 to the employees of the headquarters office.

Any physician who visits Chicago should avail himself of the opportunity to visit the headquarters office and particularly to see at first hand the service rendered by the library department. It has gradually expanded so as to occupy a new space in the headquarters office, and the need for facilities that would permit better organization and working conditions in this phase of the Association's work is obvious.

Cooperative Medical Advertising Bureau

Because of poor business conditions, the net earnings of the Cooperative Medical Advertising Bureau for 1933 were considerably less than in any of several preceding years, amounting to \$19,266.25, approximately \$5,000 less than in 1932. Of this amount, the sum of \$5,000 was distributed among the thirty-two journals of constituent state medical associations that are now being served by the Bureau, this distribution having been made in proportion to the total amount of advertising secured for each of the journals. The operating costs of the Bureau amounted to \$14,266.25.

Mailing and Order Department

The total number of orders handled by this department was 71,794, the largest ever recorded. The total number of units distributed was 237,596.

More than two million pieces of first and third class mail were sent out during the year, and 149 tons of mail other than first and third class matter were handled through the mailing department.

American Medical Directory

The publication of the Thirteenth Edition of the American Medical Directory was postponed for one year because of unfavorable business conditions. The continuance of the Directory is so essential that the work of compiling the necessary data had to be pursued without interruption, and the Thirteenth Edition has recently come from the press. This new edition contains about 10,000 new names, and it was necessary to record approximately 70,000 changes of local addresses.

Extension of Credit

The Board of Trustees, fully realizing the untoward effects of the depression on the incomes of physicians, has continued the policy of extending credit, to Fellows and subscribers who have found it difficult or impossible to make prompt payment for subscription and Fellowship dues, to the fullest possible limit permitted under the provisions of the postal regulations or the By-Laws of the American Medical Association. It has been necessary to secure statements indicating intention to pay all sums in arrears.

It is a matter of keen regret that it has been unavoidably necessary to remove names from the Fellowship roster and to terminate subscriptions.

Council on Pharmacy and Chemistry

Probably there has been no year in the history of the Council when its work has increased more rapidly than in 1933. The amount of work which the members of the Council were called on to do increased by approximately 25 per cent, whereas the work done by the office personnel was still somewhat greater. It is difficult to determine all the reasons for this increase. Certain it is that physicians are becoming more "Council minded" and inquire more uniformly of detail men who importune them to use new drugs, "Has the product been accepted by the Council?" Representatives of manufacturers have stated frankly that the greatest sales resistance with which their detail men

come in contact when introducing an unaccepted drug is that found when the physician asks that question. Furthermore the progressive manufacturer really values the advice and opinion of the Council. Increasingly the Council has become an aid to those manufacturers who wish to promote drugs honestly. There are, to be sure, some less progressive and less conscientious manufacturers who still find it possible to sell drugs to the medical profession. A number of these concerns have endeavored to submit one or two of their products in order to gain the prestige of acceptance. While a few products of these manufacturers may meet the requirements of the Council's rules their general propaganda is in such conflict with its ideals and principles that the Council has been obliged to apply rule 11, whereby no product of such concerns may be accepted unless rectification of unacceptable practices is made. During 1933 it was necessary to apply rule 11 in practically as many cases as in the combined time of the several preceding years. That this procedure has its good effects is not to be doubted, because some of the manufacturers are apparently making sincere efforts to clean house in order that they may be able to obtain the Council's action on products which they submit.

Compliance with the National Recovery Act has shortened office hours. All of this has caused such increased work for the Council office that it was necessary, notwithstanding the depression, to increase the personnel and further additions must soon be made. The office of the Council has been reorganized completely, so that under the Secretary there are three divisions, small in size but each a nucleus for further growth: (1) Editorial Department, the function of which is to edit the reports of the Council, its various books and other publications, (2) Department of Records, the chief purpose of which, as its name indicates, is to maintain the files and to abstract the various actions of the Council for future reference, (3) Department of Medicine, through which a number of well qualified physicians aid the Council members in the preparation of reports, (4) the general Administrative Department.

PUBLICATIONS OF THE COUNCIL

New and Nonofficial Remedies—New and Nonofficial Remedies, an annual publication containing the lists of products accepted by the Council, has continued to make its influence felt. Practically all class A colleges now request copies in order that their students of materia medica may become familiar with this important contribution to medical progress. New and Nonofficial Remedies is revised each year. At the close of 1933 the number of revisions due to the advance in therapeutics was relatively large. The new volume will contain many additions. Some of the older drugs that have not proved to be of much value today have been omitted. The omitted drugs at one time were considered promising but newer advances have rendered them obsolete. The Supplement to New and Nonofficial Remedies was published twice during the year, with descriptions of those products which had been found acceptable after Jan. 1, 1933. New and Nonofficial Remedies may be looked on as the only up-to-date reference book for everyday use by physicians who are interested in an unbiased statement of drugs honestly promoted, particularly proprietary products.

Few physicians realize how carefully a drug is examined by the Council before it is admitted to N. N. R. Nonbiological products must pass the most exacting tests of the A. M. A. Chemical Laboratory, and the manufacturer must agree to abide by standards mutually satisfactory to the Laboratory and the manufacturer. A number of interesting new drugs were accepted by the Council during the year such as Aminophyllin Neo Iopa, Benzadrine, Pneumococcus Serum Types I and II, Autolyzed Liver Concentrate, Extralin, Metycaine and Sodium Morrhuate.

Council Reports—The Council issues three types of reports: (a) those presenting a statement of the Council's consideration of a product rejected or omitted from New and Nonofficial Remedies; (b) those giving preliminary statements of the status of products which show promise of being useful but which are not at the time ready for acceptance and in which it is attempted to outline proper standards for products under consideration and to indicate the evidence needed to establish their usefulness in medicine; (c) those concerned with general questions of current interest to the medical profession.

The Council reports on the consideration of articles that have been submitted by manufacturers and found unacceptable are always referred to the manufacturers concerned before publication. Reports on articles that have not been submitted for consideration by the Council and that are not believed to be meritorious or that are thought to be harmful are also published, but these are not submitted to the manufacturers before publication. Reports are also issued on rejected articles, including those omitted from New and Nonofficial Remedies and those which have not borne out the promise of therapeutic usefulness under which they may have been accepted.

During the year a number of reports were published dealing with the products of relatively recent discovery. The article on estrogenic substances attracted considerable attention, being an epitomized survey of the work that has been done on female sex hormones, showing the lack of clinical evidence to warrant widespread use of these substances in pathologic conditions. The Council has given further consideration to *Bacillus bulgaricus* and *Bacillus acidophilus* preparations. An extensive examination of market specimens of these preparations is now under way. In case of *Bacillus bulgaricus* preparations, the Council felt that further inclusion in N. N. R. of such products is not warranted. The Council has reaffirmed its previous position, after extensive investigations against the intravenous use of barbitals except in certain specified conditions. The Council has also published a number of preliminary reports on new drugs, the most comprehensive being those on Dilaudid, a new morphine derivative, and on Dimitrophenol, proposed as a remedy for obesity. In the case of Dimitrophenol, inquiries on this product alone are being received in the Council office, at the time of this report at the rate of about thirty a week. Other preliminary reports were on Fuadin, a promising new antimony compound, Hipuran, a new agent for excretion urography, Vinyl Ether, a new anesthetic agent, and Kharasch Arsenical "No. 16".

Much time has been given to the consideration of antiseptics and to the further clarification of the status of Mercurochrome. During the year the Council completed its consideration of Pyridium, which was subjected to extensive investigations both by the Council and by the manufacturer, whose cooperation was commended. It was felt that the evidence did not justify the inclusion of this product in New and Nonofficial Remedies. The Council also published a comprehensive report on Clavipurin rejecting the product because of the inadequacy of its standardization and the product has been withdrawn from the American market, thus showing again the usefulness of the Council and the Laboratory in protecting the American public. There was also published under the auspices of the Council an article on the "Hospital Formulary" by Hatcher and Stainsby, which deals with methods for rational prescribing and lower costs for hospitals. This has attracted many favorable comments.

The situation in regard to the use of numbers in names of products became so acute that the Council was forced to define more explicitly the rules in reference to such names. Numbers are now entirely omitted as part of the name (title) of the drug, except when they refer to percentage or some suitably similar relationship. If this had not been done a most chaotic condition would have arisen from the confusion of numbers as means of prescribing. In some instances the Council's enforcement of this decision worked some hardship on the manufacturer, but in most instances this step was welcomed. Practically every manufacturer having dealings with the Council has been revising his labels during the past year in accordance with the Council's ruling. In enforcing this rule the Council has been lenient and the manufacturers have been given ample time to use up old stocks of labels. It is believed that therapeutics will be benefited in future years by this step.

On many occasions the Council has been called on to coin names for products which originally had unsatisfactory or therapeutically suggestive names. Whenever the manufacturer was willing to cooperate fully with the Council the Council was glad to be of service in this connection.

In the matter of removing numbers from names there arose the particular example of Hexylene. Original Solution S. T. 37. When the product was originally submitted to the Council, the Council maintained that S. T. 37 should not be preempted because it simply designated a physical property of the solution (i. e. 37 dynes per centimeter) and was no more deserving of

preemption than would be a percentage statement or a statement of specific gravity. The product was found acceptable and the firm agreed that the expression "S T 37" would not be used as a name but that the product would be known as Hexylresorcinol Solution S T 37. During this time the product was widely advertised to both physicians and the public as an antiseptic. The term "S T 37" became more widely known by the public than the name Hexylresorcinol Solution. Repeatedly it was necessary to remind the manufacturer of infractions of its agreement. When the Council decided that the rule against numbers as part of the name must be more definitely enforced, this necessitated the application of the rule to Hexylresorcinol Solution S T 37. The manufacturer could not see its way clear to accept the Council's ruling and therefore the Council was obliged to omit Hexylresorcinol Solution S T 37 from New and Nonofficial Remedies. At the time this action was considered the concern had been requested to make numerous other revisions in the advertising claims. It agreed to do this only on condition that the Council permitted the retention of the expression "S T 37" in the name. In view of the Council's refusal and the omission of the product from N N R, the manufacturer has not felt duty bound to abide by the Council's decision with reference to other claims. This simply shows some of the difficulties that confront the Council in its endeavor to protect the medical profession against unfortunate forms of drug promotion.

During the year the book "Hospital Practice for Interns" (sponsored by the Council in collaboration with the Council on Medical Education and Hospitals) has been reprinted. The Council has also collaborated with the Council on Physical Therapy in the publication of a report on oxygen therapy. Other Council publications have maintained their position in the medical profession particularly "Useful Drugs" the sale of which is encouraging. The "Epitome of the U S Pharmacopoeia and National Formulary" also finds ready use by those practicing physicians who desire information concerning drugs listed in the U S Pharmacopoeia and the National Formulary.

COUNCIL MEMBERSHIP

No new members were elected. The members whose terms expired last year were reelected.

On Dec 5, 1933, the Council lost by death one of its most valued members, Dr Alfred Fabian Hess. Dr Hess had served on the Council since 1932 and had been most devoted to this phase of the Association's activities. His wise counsel on matters that affected new advances in the vitamin field and calcium therapy was most helpful.

The Chemical Laboratory

Because of the increasing number of products submitted to the Council on Pharmacy and Chemistry, the work of the Chemical Laboratory has been correspondingly larger. There was no original investigative work undertaken during the year, because the personnel of the Laboratory was overtaxed with current problems.

WORK FOR THE COUNCIL

The Laboratory has examined and elaborated standards for a comparatively large number of new additions to modern *materia medica*, such as Neo Iopon, a new contrast medium; new barbitol preparations, such as sodium alurate and oral sodium, and also for various brands of sodium morrhuate. It has also continued its study of phenobarbital and phenobarbital sodium. The difficulties of fixing standards are in some instances greatly increased because of the nature of the products concerned, as in the case of benzedrine, somewhat similar to ephedrine, but differing physically in that certain of its salts are volatile. Beta-lactose, which differs from alpha-lactose (a common milk sugar) was standardized and definite crystalline optical properties as means of differentiation were determined. As was the case last year, the investigation of bismuth compounds used in syphilis required considerable time on the part of one chemist. The examination of new local anesthetics and new glucosides for use in treating ailments of the heart has been continued. The Laboratory has also examined sandalwood oil and elaborated standards for halibut liver oil as well as for triethanolamine. As usual, a number of products were

rejected by the Council on account of adverse findings of the Laboratory.

OTHER WORK

The Laboratory has continued to cooperate with the Bureau of Investigation in investigating certain nostrums sold to the public. It has also continued to serve the other departments of the Association, particularly the editorial department and the *QUARTERLY CUMULATIVE INDEX MEDICUS*. The members of the staff have published articles in leading scientific publications and have delivered addresses dealing with medicinal chemistry before a number of scientific organizations, universities and schools.

Council on Physical Therapy

The value of physical therapy in the everyday practice of medicine is being more generally recognized and the proper application of its methods is becoming better understood as the observant experience of physicians has been developed and the research in this important field has been extended. Many of the best hospitals are now adequately equipped in their departments of physical therapy, and through the work of these departments a most valuable contribution is being made to the store of scientific knowledge. The Council on Physical Therapy is engaged in earnest efforts to evaluate properly the therapeutic influences, both helpful and harmful, emanating from the application of physical forces.

In ultraviolet therapy the Council has made a careful review of medical literature and has invited research by specialists on controversial questions to determine its efficacy. Some of the important results of the Council's investigations have been incorporated in its revised "Regulations to Govern Advertising of Ultraviolet Generators to the Profession," which have been published in *THE JOURNAL*. Cooperation has been secured from the Council on Dental Therapeutics of the American Dental Association in an attempt to determine the therapeutic efficacy of ultraviolet therapy in dental conditions. Research both clinical and scientific, has been sponsored under the direction of both councils. An abstract of this report, of interest to physicians as well as dentists, has appeared in *THE JOURNAL*. In the matter of standardization, the Council has cooperated with the International Congress on Light by adopting its suggested standard unit of dosage for therapeutic practice.

Much time and effort have been given to investigations of diathermy apparatus. Because of the lack of critical research on the therapeutic effects of heat generated by diathermy, it has been difficult to evaluate the claims made for the equipment. The Council has stimulated and has assisted in carefully conducted clinical investigations and research designed to lead to a better understanding of this method. The publication of the articles "Diathermy—A Preliminary Statement to Acceptance of Diathermy Apparatus" and "The Examination of Diathermy Machines for Local Diathermy Treatments and Requirements for Acceptance of these Machines by the Council on Physical Therapy of the American Medical Association" has led to a saner interpretation of the value of diathermy. In the fields of electrocoagulation and surgical cutting currents, substantial progress has been made.

The Council has investigated resuscitation equipment and oxygen tents and has published reports concerning these products and has thus developed much needed information.

During the past year the Council has investigated and considered sixty eight devices and pieces of apparatus, of which one fifth have been reported on in *THE JOURNAL*. The others are still under consideration. In many instances these investigations have required more than a year to complete. This time is necessary because of the complexity of the problems involved. The Council cannot afford to accept an electrical apparatus until it has been thoroughly tested with reference to insulation, safety and efficiency. Some of the investigations have terminated in reports of nonacceptance and these reports have been submitted to the manufacturers prior to publication in accordance with the method of procedure of the Council. In most instances the manufacturers asked that the reports be held in abeyance until the objectionable features could be corrected and the rules of the Council met. Ethical firms generally appreciate the educational value of these reports.

Under the existing rules there are a large number of devices that might be considered to come within the purview of the Council. To facilitate the work with due efficiency and dispatch, two lists of devices have been formulated. One is a list of apparatus and devices that the Council will consider and report on as soon as possible, and the other contains the names of articles that cannot be given immediate consideration. The Council's refusal to consider any product should never be considered as a condemnation.

One of the important activities of the Council is in connection with the promotion of sound education in physical therapy. Exhibits and demonstrations of physical therapy at the annual session have been used to promote better physical therapy practice among the profession. These exhibits appear to have accomplished a useful purpose. Exhibits have been made at several scientific meetings of other professional societies. The cooperation of several societies interested in physical therapy has been enlisted in the formulation of essentials of educational requirements for schools of physical therapy and occupational therapy technicians. The Council on Medical Education and Hospitals is cooperating with this council in the formulation of essentials for physical therapy and occupational therapy schools.

The cordial cooperation extended by many of the producers of physical therapy apparatus in bringing advertising and descriptive literature more in line with statements of fact is most gratifying. The objectionable practice of manufacturers holding clinics, which for the most part are 25 per cent, more or less, instruction and 75 per cent sales promotion, has been largely discontinued. To aid manufacturers in the accumulation of acceptable evidence with reference to the value of the products, the Council has adopted the article "Evaluation of Methods Used In Physical Therapy," which has been published in *THE JOURNAL*.

Greater emphasis on education is scheduled for the coming year. The Council is planning to assist state associations interested in creating special committees within the societies. It is the hope of the Council that these committees will hold seminars for the postgraduate instruction in physical therapy for the practicing physician. At the present time the need of physical equipment in offices and clinics is not so important as dissemination of information, among the practicing physicians concerning the proper application of acceptable physical therapy methods that are readily available to all physicians. The desire of physicians to obtain more information about physical therapy agents is clearly shown by the fact that the correspondence of the Council has constantly increased.

Through an annual appropriation made by the Board of Trustees, the Council has awarded grants to a number of critical investigators. These grants have all been relatively small in amount and have been used for the purchase of needed materials. Money is not available for the salaries of the workers. The results of the work done under these grants have been encouraging.

Bureau of Medical Economics

An increased interest and activity in the field of medical economics has been observed in many sections of the United States throughout the past year. Although many lay interests have continued their activities in medical economics there has been a marked increase in the number of proposals and schemes offered by individuals and groups within the medical profession to modify the established form of medical practice. Some of these new proposals involve types of organization and methods of practice that are contrary to the generally accepted views of the profession on the corporate practice of medicine and contrary to the principles of medical ethics governing solicitation. In some instances it appears that the methods adopted are those of desperation. In these instances one is justified in raising the question whether a temporary expedient will bring to the public and to the medical profession greater benefits than are represented by the social values in medicine which some of these plans are sure to destroy.

CONTRACT PRACTICE

The study of contract practice schemes has continued through the year. In the files of the Bureau 570 contract practice plans are on record representing proposals that have never

been placed in operation, schemes that have been operated for only a short period, and plans that seem to have assumed a more or less permanent status. The greatest activity in the field of contract practice during 1933 was found in group hospitalization. During the year, about forty different proposals from widely separated sections of the country were prepared. Many of these schemes were never placed in operation, but there appears to have been a gradually increasing movement in this direction.

This movement has been encouraged by the action of the American Hospital Association and by certain individuals and foundations having no official connection with the medical profession.

An analysis and criticism of hospital insurance schemes has appeared in two articles in *THE JOURNAL*, and one article in the *BULLETIN*.

THE PRACTICE OF MEDICINE IN CUBA

In compliance with the desire of the House of Delegates to secure detailed first-hand information concerning the conditions surrounding the practice of medicine in Cuba, a study was made in March 1933 of the Cuban medical organization and of the Mutualist Societies in Cuba.

An abbreviated report of that study was published in June in *THE BULLETIN*.

WORKMEN'S COMPENSATION

Until recently the largest system involving the practice of medicine with legally established benefits was the system of workmen's compensation. In many of the states the methods used to provide medical care for injured workmen closely resembled sickness insurance. During the period over which workmen's compensation laws were enacted in the forty-four states in which it now operates, comparatively little attention was paid to the medical phases of compensation. In the past two decades the medical phase of workmen's compensation has constantly increased in importance. The report on "Medical Relations Under Workmen's Compensation," published in March 1933 is an analysis of the development of the medical services under workmen's compensation laws.

GROUP PRACTICE

The Committee on the Costs of Medical Care prepared a report entitled "Private Group Clinics," publication 8. In this publication an attempt was made to describe the administrative and economic aspects of group medical practices as represented in the policies and procedures of fifty-five private associations of medical practitioners. This report was issued in January 1931.

Soon after the organization of the Bureau of Medical Economics, schedules on various topics were sent to the secretaries of county medical societies. Among these schedules was one asking for information on group practice. Based on the information received on these schedules a second questionnaire was sent to all those secretaries who reported the existence of one or more groups within the jurisdiction of their societies. The data supplied by county medical society secretaries provided a list of more than 500 organizations thought to be medical groups. Additional lists from other sources raised the number to 724.

One of the chief difficulties in the early part of this study was to prepare a definition of group medical practice. Letters and questionnaires brought information showing that about one half of the 724 reported groups did not conform to a sufficient number of the standards that had been set up to define group medical practice to entitle them to inclusion in this study, although many of these called themselves clinics and were so considered in their localities.

From all the information received it was determined that there were more than 300 groups within the United States that would come within the classifications set up for the study. Of these 239 filled out a special questionnaire in a sufficiently complete form to provide data suitable for study. These groups were located in thirty-seven states and in communities varying in population from less than a thousand to a million and over. The report of this study was reprinted with additions from the issues of *THE JOURNAL* of May 20, May 27 and June 3, 1933.

COLLECTION AGENCIES AND METHODS

The consideration given to collection agencies and methods is a continuous process of study and investigation. The number of collection agencies that deal with medical accounts now on record in the Bureau is 1110.

Early in 1933 the Bureau undertook a study of collection agencies and credit bureaus owned and operated by county medical societies. It appears from information gained in this study that more satisfactory results are obtained by the collection agencies and credit bureaus owned and operated by medical societies than by the use of the ordinary commercial collection agencies and methods. The report of this study appeared in *THE JOURNAL*, June 17, 1933.

MEDICAL FEES

Information is now being compiled concerning the fee schedules of county medical societies. The data, from 372 counties in forty-four states, is being assembled to show the minimum and maximum fees as reported by these county medical societies.

INSTRUCTION IN MEDICAL ECONOMICS

One of the objectives sought by the Bureau of Medical Economics ever since its organization has been to make available to medical students, as well as to practicing physicians, a statement of the principles that should govern the economics of the practice of medicine. The economic methods involved in the practice of medicine are too often likely to be changed to satisfy a temporary or emergency situation. Modification of the methods of medical practice must conform to certain definite principles if they are to preserve the social values in medical service that have required thousands of years to establish. The responsibility of the medical profession does not end with the correction of medical economic abuses when they are found. The medical profession must assume the further responsibility of informing the oncoming generations of young physicians in the correct principles of medical economics.

An "Introduction to Medical Economics" was prepared and issued in October 1933. This publication for the first time set forth the principles surrounding the economics of the profession and endeavored to differentiate between the economics of industry, commerce and business, and the economics of professional services.

HEALTH AND ACCIDENT INSURANCE PRACTICES

At the last session of the House of Delegates, the proposed short form for reporting health and accident insurance claims was approved. At the annual meeting of the International Claim Association during the middle of September 1933 the short forms prepared by the International Claim Association Committee on Attending Physicians' Claim Statements, with which this bureau has been working, were presented for consideration. These forms were approved and adopted by the International Claim Association. The Claim Association Committee was continued by that association, with power to act. The committee is now proceeding with authority to bring about the adoption of these new short forms by the individual companies that participated in the study.

The work of the Committee on Attending Physician's Claim Statements has been of no less importance to the medical profession than to the insurance companies. The cooperation between that committee and this bureau has been at all times most harmonious. There are many questions of mutual interest and importance pertaining to insurance practices that may profitably be studied jointly by the International Claim Association and the Bureau of Medical Economics, and it seems probable that a much more intelligent understanding of the motives and desires of both associations may result from this working agreement.

CARE OF THE INDIGENT SICK

At present the Bureau of Medical Economics is engaged in a study of the history, development and current practices in the medical care of the indigent. The response by the secretaries of state medical associations and others to requests for information on this subject has been gratifying. This study will require several months more to complete.

No little confusion has resulted throughout the United States among the members of medical societies over the regulations,

agreements, changes of policy and reversals of plans connected with the Federal Emergency Relief Administration, the Civil Works Administration and the Federal Transients Bureau program. This bureau has endeavored to offer such assistance as it could to state and county medical societies in the preparation of agreements to provide medical service under federal regulations so safeguarded that the fundamental values of medical service might not be destroyed and that dangerous precedents might not be established.

A REPORT ON HEALTH INSURANCE

Sources. All literature available in the medical magazines especially of the last three years, and in the Crerar and University of Chicago libraries has been consulted. In addition practically all works reviewed or advertised in German medical publications during the last two years were purchased. A special mass of material consisting of laws, reports and pamphlets was collected by a special representative in Austria. There was also available all the material that was collected as the basis of writing "The Way of Health Insurance." Not much use was made of this material, however, since an effort was made to avoid duplication of any part of that work and especially to emphasize developments since that was written. Questionnaires were sent to all the correspondents of *THE JOURNAL* requesting information as to the working of sickness insurance in the various countries. A copy of that questionnaire is appended. Considerable use was made of this information not only in some direct quotations but also in checking conclusions based on other sources.

Summary of Report. The subject matter of the report may be generally indicated by the titles of the various chapters, which are as follows:

- 1 Conditions at Beginning of Sickness Insurance
- 2 Changes in Institutions and Objectives
- 3 Medical Service
- 4 The Physician in Sickness Insurance
- 5 Some General Professional and Social Effects

A historical sketch shows the social origins of insurance and traces the process by which a system organized primarily for cash relief became a system of medical service, while setting up institutions in no way suited to operate such a service. This development influences all present proposals for insurance. Systems of insurance became political instruments for the purchase of votes through increased benefits, with little regard to medical necessities.

There is considerable discussion backed by thorough documentation of the way in which sickness insurance increases the "morbidity" as measured by cash payments for days of labor lost. The evidence is furnished from neurologists and psychiatrists in insurance countries as to the tendency of insurance to create neuroses. It is also shown that the medical service tends to become perfunctory and to cause increased medication and excessive use of such treatment as can be given mechanically, and to excessive hospital service.

When a system has continued long enough for the insured to have paid in considerable sums, it is shown that there arises a general desire on their part to "get their money back," which greatly increases the demand for unnecessary medical service and causes a conflict between the insured, the physicians and the administrators of insurance systems which makes any scientific diagnosis and treatment difficult. This attitude is aggravated by the desire to obtain cash benefits, but it extends also to dependents who receive no cash.

Considerable stress is laid on the tendency of insurance to increase lay control of medical service and to show that this is a universal policy of the insurance administrators and of advocates of insurance in this country.

It is shown that these tendencies are most evident in the older systems and increase with time. Methods of payment of physicians and conditions of admittance to insurance practice are explained. The character of medical service is illustrated by quotations from medical writings, as is also the effect of insurance on graduate education.

There is an elaborate tabulation of the different medical forms of insurance in the various countries which makes clear at almost a glance just what is the character and the extent

of the medical service given in all leading insurance countries. There is no definite conclusion for or against insurance further than to make it clear that existing systems of insurance have failed to solve the problem of medical care for the people and have brought a great many evils along with some benefits. The question is raised and evidence cited to indicate that the huge sums necessary for insurance might be expended in other forms of health care with much greater effect. A large number of recent writers are cited to show that there is widespread movement in insurance countries to substitute for sickness insurance some form of compulsory saving with payment of an immediate sum for their medical services and the return of a portion of unused savings for insurance needs.

The question of the practicability of the insurance method in supplying medical care is discussed, and it is shown by documented evidence that insurance has nowhere reduced morbidity, that no actuarial basis has ever been set up that has not been proved defective, and that the vast sums required for insurance and the dominance of such systems in the political social life of a country tends to focus attention on insurance to the exclusion of other forms of effort and therefore indicates that it is not the most effective method of meeting the problems of medical care for the mass of the people.

MISCELLANEOUS ITEMS

The foregoing has necessarily been only a brief statement of the activities on the major phases of medical economics during the past year. Numerous other medical economic questions have occupied more or less attention.

A series of tables are almost complete, showing the distribution of physicians in each state, by size of community, according to the type of practice of each physician. Those physicians who are retired or not in practice have been removed from the active list in the tables.

Tables have also been secured showing the distribution of Negro physicians in the various sections of the United States. These tables also show the number and percentage of graduates of Negro physicians from the medical schools in which they were trained, the distribution and ratio of physicians to population by districts and race, the ratio of both Negro and white physicians to population according to states, and the ratio of Negro physicians to population in cities above and below 50,000 population.

Most discussions of medical economics touch at some points the subjects of medical organization and the principles of medical ethics. The chairman of the Judicial Council has been consulted repeatedly on specific questions dealing with medical ethics.

It has been necessary to give some attention to that phase of hospital practice which involves the services of the clinical pathologist, the anesthetist and the roentgenologist. In many hospitals these services particularly that of roentgenology are used to provide an income profit to the hospital with which deficits in other departments may be met. This practice necessarily involves the question of utilizing the skill and experience of a physician at a nominal fixed salary for the accumulation of profit to the institution. This is receiving serious consideration in a number of sections of the United States and will no doubt become a medical economic question of increasingly greater importance.

There is a definite medical economic phase to many of the practices that have become prevalent in the programs of health departments and boards of education. Attempts are being made in some sections of the country to correct these practices and to return to the private practicing physician some of the work formerly done by these departments but which always belonged to the practicing physician.

In some sections of the United States plans for part pay clinics are being studied or proposed as a relief for some of the general economic unrest. This question also will no doubt become of more importance.

The activities of universities and colleges in providing health or medical services to their students have a definite medical economic bearing. A study of this subject has been initiated and a report will appear as soon as the data can be assembled and studied.

FIELD WORK

The following represents the field work for 1933

- One hundred and twenty four days away from the office
- Fifty two scheduled talks before medical society meetings aggregating more than 5900
- One hundred and seven conferences in the United States and Cuba with more than 650 physicians
- Eighteen states visited
- Twenty-eight cities in the United States and six cities in Cuba visited

In addition to the foregoing field work by the director, Mr. Simons, the assistant director, made visits to Washington New York, Boston and Pittsburgh, to collect data for the study on "Medical Relations Under Workmen's Compensation."

OFFICE ROUTINE

In the office routine, 2,168 communications were handled the majority of these being on the subjects of medical economic instruction, group practice, contract practice, care of the indigent sick and collection agencies and methods.

PLANS FOR THE PRESENT YEAR

Some of the major activities contemplated for the Bureau of Medical Economics for 1934 are

- 1 To continue the study and criticism of contract practice schemes
- 2 To continue and complete the study on the medical care of the indigent
- 3 To initiate the study of new problems in the field of health and accident insurance practices
- 4 To complete the study on health insurance
- 5 To complete the study of university and college student health services

QUESTIONS TO STATE SECRETARIES ON CARE OF THE INDIGENT SICK

- 1 What is the legally provided method of furnishing medical care to the indigent in your state?
- 2 If your state has published a summary of the poor laws where may a copy be obtained?
 - A What is the governmental unit charged with the provision of medical care for the indigent? (Name of official or body)
 - (a) County
 - (b) Township
 - (c) City
- 3 What standards of indigency have been established?
- 4 What is the method of payment for medical care for the indigent?
 - A Contract with individual—
 - (a) County physician
 - (b) Township physician
 - B Are they paid for full time or part time services?
- 5 What are the duties of such employed physicians? (Full or part time)
 - (a) Care of institutional poor (jail—poorhouse—children's homes or orphanages)
 - (b) Outpatient (home) care
 - (c) Health officers
- 6 How fully do employed county or city physicians meet the local demand?
- 7 What arrangements are made to pay for medical care in addition to that furnished by county, city or township physicians?
- 8 Have any county medical societies in your state contracted with county or city officials to render medical care to indigents? (If so please give list of such county medical societies)
- 9 What actions have county medical societies taken with respect to medical care of the indigent aside from such contract?
 - (a) Established fee schedule
 - (b) Cooperation with authorities
 - (c) Any other actions
- 10 What changes have been made in methods of medical care for indigents during the past four years?
- 11 Is the present system satisfactory?
- 12 Was it satisfactory before 1929?
- 13 What are main defects?
- 14 Has the state medical association or any county medical society made any special study of the care of indigents?
 - A If so is the result of the study or studies available?
- 15 What if any arrangements have been made by the state medical association or county medical societies with emergency relief bodies? (For example The Federal Emergency Relief Administration)

Please end complete file of regulations forms used contracts agreement rules of procedure etc for the Bureau of Medical Economics file

QUESTIONS FOR CORRESPONDENTS ON SICKNESS INSURANCE

- How does health insurance affect the individual physician as to income?
- What is the average or median income of insurance physicians?
 - (a) In the city?
 - (b) In the country?

Are insurance incomes supplemented from private practice?
How?
To what extent?
What has been the general effect of sickness insurance on the profession as to
Public confidence?
Medical education?
Graduate work and research?
Have the medical insurance records of patients been of any value in medical or economic research?
Has the character of medical service been changed under sickness insurance?
Does the method of diagnosis under sickness insurance differ from that used in private practice?
Is there any change in the extent of use of laboratory procedures?
Treatment: Is there an increase or a decrease of medication?
Have hospitals, clinics, laboratories, etc. been unduly expanded?
Are they controlled by the medical profession or by insurance funds?
Is treatment interfered with by insurance authorities? If so how?
What has been the effect of sickness insurance on professional organization?
Is there an economic as well as a scientific organization of the medical profession?
What is the attitude of the medical profession toward the sickness insurance system?
What criticisms are made of sickness insurance?
What have been the effects of sickness insurance on patients as to
Amount of sickness?
Length of sickness?
Confidence in profession?
Patronizing quirks?
What has been the effect of combining cash and medical benefits?
How does giving sickness certificates effect the relations of physician with patient?
What if any has been the effect of sickness insurance on medical research and the individual initiative of physicians?

Bureau of Legal Medicine and Legislation

FEDERAL LEGISLATION

The special session of the Seventy-Third Congress convened March 4, 1933, and adjourned June 16, 1933. The first regular session convened Jan. 3, 1934, and is still in progress; this report is being written (March 15). The Bureau of Legal Medicine and Legislation has kept in touch with legislation proposed in Congress and with various administrative rules and regulations of interest to physicians proposed by the National Recovery Administration, the Federal Emergency Relief Administration, the Federal Civil Works Administration, the United States Employees' Compensation Commission and other branches of the government. Copies of bills of interest have been obtained and timely notice has been given through THE JOURNAL of their introduction and of subsequent action if any, with respect to them. Administrative regulations and orders have been communicated to the profession through THE JOURNAL as promptly as practicable. Special communications with respect to these matters have been sent to the officers of state associations as circumstances warranted. The Bureau prepared and published in the AMERICAN MEDICAL ASSOCIATION BULLETIN, November 1933, a summary of the federal legislation acted on by Congress during the year, or then pending. The director of the Bureau has spent a great deal of time in Washington to confer with federal officials and to appear before congressional committees. Some of the more important phases of the Bureau's activities in connection with federal legislation are discussed below.

NATIONAL INDUSTRIAL RECOVERY ACT

On June 16, 1933, the President approved the National Industrial Recovery Act, frequently referred to as NIRA. It authorized the President, on the application of trade or industrial associations or groups, to approve codes of fair competition for the trades or industries represented by the applicants. It authorized the President, too, to enter into agreements with, and to approve voluntary agreements among, persons engaged in a trade or industry, labor organizations, and trade and industrial organizations, associations or groups, relating to any trade or industry, if in his judgment such agreements would further the purpose of the act with respect to transactions in or affecting interstate or foreign commerce. The act made no provision for the regimentation of any profession under any code or agreement. On the other hand, it did not forbid any member of any profession from becoming a party to any agreement that the President might propose.

On July 20, 1933, the National Recovery Administrator, with the approval of the National Industrial Recovery Board, pro-

mulgated the "President's Reemployment Program." As a part of that program the "President's Reemployment Agreement" was issued, fixing maximum hours of work and minimum rates of pay for the guidance of all who signed the agreement, all of whom pledged themselves to support and patronize others party to the agreement and listed as members of the National Recovery Administration. The agreement was to be operative only from Aug. 1 to Dec. 31, 1933.

The Executive Committee of the Board of Trustees, at a meeting Aug. 4, 1933, considered all possible implications of the National Industrial Recovery Act with respect to the medical profession. The nature of the Association and its relation to matters covered by the act were set forth by the Secretary in a letter to the National Recovery Administration, Aug. 7, 1933, and the administration was requested to furnish interpretations of the act as applied to medical organizations and to the practice of medicine, in order that the Association might do anything within its power to uphold the hands of the government. A brief reply was received under date of August 25, but most of the questions propounded have not yet been officially answered, although they have settled themselves or are settling themselves in the course of experience.

The Board of Trustees did not deem it wise to sign the President's Reemployment Agreement on behalf of the Association. The Board has not deemed it expedient to sign any code. It has endeavored however, to keep every activity of the Association well within not only the letter but also the spirit of the National Industrial Recovery Act and will continue to do so.

Private Practitioners and the National Industrial Recovery Act—Moral and social pressure, plus the possible withdrawal of patients implicit in the obligation of signers of the agreement to support and patronize other signers of it, led many physicians to become parties to the agreement. From other physicians came appeals for information as to the policy of the American Medical Association with respect to the matter. In view of the wide diversity of conditions under which medicine is practiced in the United States, it did not seem possible to advise physicians generally to become parties to this agreement without defeating the very purpose of the National Industrial Recovery Act. One of the declared purposes of the act is to eliminate unfair competitive practices. The display of the Blue Eagle by a physician a party to the agreement was in effect notice to every other person in the community who had signed the agreement to support and patronize that physician and other Blue Eagle physicians, in preference to all others, even though those physicians, because of financial conditions, could not become parties to the agreement. Waiving any question as to the professional ethics involved in such a procedure the fact that this tended to promote unfair competitive practices and not to eliminate them, as the act proposed, is obvious.

Physicians who inquired whether they should or should not become parties to the President's Reemployment Agreement were therefore advised to take the matter up with their county medical societies with a view to having the society determine whether, under conditions then existing in the community, the signing of the agreement was compatible with fair professional competition. It was suggested that if the society found that physicians by becoming parties to the agreement, promoted unfair competition the society should if possible suggest to the National Recovery Administration such changes in the agreement as would render it susceptible of being signed by every physician consistently with its purposes and the purposes of the National Industrial Recovery Act, in order that every physician in the community might be able to sign it with justice to all others.

Physicians Employees—Notwithstanding the fact that physicians in their professional capacity, were not within the purview of the National Industrial Recovery Act or of the President's Reemployment Agreement, it was contended by some of the officers connected with the National Recovery Administration that physicians' employees were covered by the agreement, except that professional employees were exempted from the maximum hour requirements. Since the agreement expired by limitation Dec. 31, 1933 the question whether the medical profession could be brought within its terms by the simple

expedient of bringing employees of the profession within its terms is now of only academic interest. But until the practice of medicine has become a trade or an industry, the medical profession will not be within the purview of the National Industrial Recovery Act.

Hospitals—Under the National Industrial Recovery Act and the President's Reemployment Agreement the question whether hospitals came within the purview of the act arose. After some early misunderstanding about the matter, Mr. Donald R. Richberg, General Counsel, National Industrial Recovery Administration, Aug. 17, 1933, ruled that hospitals not engaged in carrying on a trade or industry do not come within the purview of the act so as to come under the ordinary requirement of a code of fair competition.

Röntgenologic Laboratories—Owners and operators of clinical and roentgenologic laboratories in certain localities sought to take advantage of the provisions of the National Industrial Recovery Act and initiated movements to procure the adoption of a code. They seemed willing to admit that they were engaged in a trade or industry not in the practice of a profession. How the activities of such laboratories constituted transactions in or affecting interstate or foreign commerce does not appear. So far as is known no responsible group of roentgenologists or of proprietors of clinical laboratories, whether professional men or laymen organized on a national scale, has sought to procure the adoption of a code to cover their activities. Such codes as have been proposed by local groups have not been susceptible of consideration by the National Recovery Administration because the proponents were not truly representative of a trade or industry.

Osteopathic and Chiropractic Codes—So far as is known the osteopaths of the country have made no effort to procure the approval of a code of fair osteopathic practice. Some of the chiropractors, however, have sought without success to procure the adoption of a chiropractic code.

Optometric Code—The American Optometric Association, although professing to be a professional organization, has subjected itself and its members to the Optical Retail Code.

Other Codes—To prevent trade and industries from trenching on the practice of medicine, through trade and industrial codes, it has been necessary for the American Medical Association to keep in active touch with the formulation and approval of such codes. Among those to which particular attention has been given are the codes for the retail drug trade, the optical retail trade, and the package medicine industry. Incidental attention has been given to codes in other trades and industries relevant to medical practice and suggestions have been made from time to time with a view to having such codes promulgated in forms not inconsistent with the normal practice of medicine and consonant with the public good.

It is a pleasure to report the uniform courtesy that the American Medical Association received at the hands of the National Recovery Administration and the broad understanding and cooperation manifested by the administration and its officers in dealing with problems of medical hospital and laboratory practice.

FEDERAL EMERGENCY RELIEF ADMINISTRATION

The Emergency Relief and Construction Act of 1932—On July 21, 1932 the President approved the act now known as the Emergency Relief and Construction Act of 1932. For the relief of destitution, title I of the act authorized the Reconstruction Finance Corporation to make available to the several states and territories out of the corporation's funds three hundred million dollars to be used in furnishing relief and work relief to needy and distressed people and in relieving the hardship resulting from unemployment. The amounts advanced were loans, to be repaid to the corporation through annual deductions from such future federal allotments as might be made to aid the debtor states or territories in the construction of highways and rural post roads. The act failed to effect the necessary relief.

Federal Emergency Relief Act of 1933—On May 12, 1933 the President approved the Federal Emergency Relief Act of 1933. This act repealed so much of the Emergency Relief and Construction Act of 1932 as related to loans to states

and territories by the Reconstruction Finance Corporation for the purposes stated in the preceding paragraph. It directed the Reconstruction Finance Corporation to make available to the Federal Emergency Relief Administration created by the act, out of the corporation's funds, not to exceed five hundred million dollars in addition to the unexpended balance of the state and territorial relief fund provided by title I of the Emergency Relief and Construction Act of 1932. The new act provided that the Federal Emergency Relief Administration should cease to exist two years after date of its enactment. Out of the funds made available by the act, the Federal Emergency Relief Administrator was authorized to make grants to the several states as gifts not as loans, "to aid in meeting the costs of furnishing relief and work relief and in relieving the hardship and suffering caused by unemployment in the form of money, service materials, and/or commodities to provide the necessities of life to persons in need as a result of the present emergency, and/or to their dependents, whether resident, transient, or homeless." These grants were to be made on a proper showing of necessity by the governors of the several states and territories and a proper showing that provision had been made to assure adequate administrative supervision and suitable standards for relief. Mr. Harry L. Hopkins was appointed Federal Emergency Relief Administrator.

As Federal Emergency Relief Administrator, Mr. Hopkins promptly recognized that adequate relief implied medical service for sick and injured persons unable to provide it at their own expense or to obtain it through state or local agencies. He promptly set about formulating rules to govern the use of federal funds for medical relief purposes conferring with a representative of the American Medical Association as he did so. The rules formulated were promulgated as Rules and Regulations No. 7 Federal Relief Administration Governing Medical Care Provided in the Home to Recipients of Unemployment Relief. These rules and regulations were almost unique, in that they sought to maintain the traditional family and family physician relationship, in the treatment of indigent persons in their homes. They recognized, too, organized medicine as the best channel through which to approach the problem of providing medical relief of the destitute sick. In the assigning out the program of medical relief the Federal Emergency Relief Administrator threw a great responsibility on organized medicine and gave it the opportunity to justify itself by its works before the Federal Emergency Relief Administration and before the public. It is believed that in the main the organized profession has done so. The misunderstanding and friction that have occurred have been insignificant in comparison with the magnitude of the work done and only such as may be looked on as normal, when the personal element is involved in an undertaking of this kind and size.

The fees paid under the Federal Emergency Relief Act have seemed often to be pitifully inadequate, but this it is said, has been the result of financial necessity. The medical profession has accepted the situation with grace and, in keeping with its traditions, has let no one suffer for lack of medical service even when it regarded the fees tendered so small that they could not be accepted with professional self respect and gave its services free. In one other respect the program of the Federal Emergency Relief Administration can be said to have fallen far short of the ideas of the officials of the American Medical Association as to what it should be—the failure on the part of the Administration to provide for the care of the destitute sick and injured in hospitals when hospital service has been necessary. This has been unfortunate. It is necessary to recognize however, in this connection, the necessity for conserving the money available for relief and to give weight to the experience of the administrator who when he promulgated regulations denying hospital services at federal expense had never met a case in which state and local agencies had failed to provide hospital service when necessary.

As this report is being prepared the Federal Emergency Relief Administration is still functioning. Contrary to a wide spread misunderstanding it was not replaced by the Federal Civil Works Administration which will now be discussed. Persons who are in need of medical services in their home and who are unable to work or if able to work unable to find

employment that will enable them to provide medical services for themselves and their families, can still be cared for through the Federal Emergency Relief Administration

FEDERAL CIVIL WORKS ADMINISTRATION

The Federal Civil Works Administration was created under the National Industrial Recovery Act, approved June 16, 1933. Title II of that act authorized the President to create a Federal Emergency Administration of Public Works and to establish such agencies as he might find necessary to effectuate its purposes. It authorized the proposed Federal Emergency Administrator of Public Works to prepare a comprehensive program of public works. The program authorized by the act contemplated the employment of considerable numbers of men on public works undertaken to create employment. Projects looking toward the construction and maintenance of public works, however generally require surveys, the preparation of plans and specifications, competitive bidding, and the award of contracts, before employment on any large scale can be effected. A sufficient increase in employment under the act was therefore slow in developing, and winter was approaching. To provide employment quickly for as many unemployed persons as possible, and to take as many persons as possible off the relief rolls, the President, Nov. 7, 1933, under authority of the act, created the Federal Civil Works Administration and appointed as its Federal Civil Works Administrator Mr. Harry L. Hopkins. Mr. Hopkins was thus vested with the duties of this new office in addition to his duties as Federal Emergency Relief Administrator. To finance the activities of the Federal Civil Works Administration, the Board of the Federal Emergency Relief Administration of Public Works allocated to it four hundred million dollars. The Federal Civil Works Administration was to provide regular work on public works at regular wages for unemployed persons able and willing to work. To do this it was to undertake to carry out by day labor, and not by contract, all public works projects of the character theretofore constructed or carried on either by public authority or with public aid, to serve the interests of the general public provided such projects were (1) socially and economically desirable and (2) susceptible of being undertaken quickly. State and local Civil Works Administrators were promptly appointed, and within a few weeks, according to published reports, more than four million men and women were put to work.

Under the organization adopted by the Federal Civil Works Administration, every man and woman put to work became an employee of the federal government. Under the provisions of the United States Employees' Compensation Act, approved Sept. 7, 1916, as amended, he or she became entitled to certain benefits for any disabling injury or disease sustained in the performance of duty, his or her surviving spouse became entitled to certain benefits if the employee's death occurred in the performance of duty, and in any event an injured employee was entitled to "all services, appliances, and supplies prescribed or recommended by duly qualified physicians which, in the opinion of the [United States Employees' Compensation] commission are likely to cure or to give relief or to reduce the degree or the period of disability or to aid in lessening the amount of the monthly compensation." Medical services, appliances and supplies, however, had to be furnished "by or upon the order of United States medical officers and hospitals" and where this was not practicable, "by or upon the order of private physicians and hospitals designated or approved by the commission." The United States Employees' Compensation Act had been in effect since 1916, and when the Federal Civil Works Administration was established, some four thousand private physicians throughout the country had been already designated or approved by the commission to treat injured federal employees when and where United States medical officers and hospitals were not available. These designated physicians were, however, obviously inadequate in number and distribution to render the service legally required for the four million and more federal employees suddenly added to the federal pay rolls.

In order to comply with the statutory requirement that service be rendered by physicians designated by the United States Employees Compensation Commission, it was proposed to the commission, on behalf of the American Medical Association that all members of the Association be thus designated or

approved by the commission, without prejudice to the right of any nonmember physician to submit to the commission evidence of his fitness and to be designated or approved. In the end, however, the commission and the Federal Civil Works Administration, both of which had substantial official interests in the matter, agreed to direct their state and local representatives to cooperate with state and county medical societies in selecting from the physicians in their respective communities those desiring to treat the sick and injured workers on the terms laid down in the regulations and competent to do so. In formulating these regulations and an agreement with representative national hospital associations as to hospital services required under the act, the American Medical Association was actively represented.

Notwithstanding the very considerable funds available in the first instance for carrying out the Federal Emergency Relief Act of 1933 and the civil works program under the Federal Civil Works Administration it became necessary to appeal for more funds. In response to that appeal, by an act approved Feb. 15, 1934, there was appropriated nine hundred and fifty million dollars, to remain available until June 30, 1935. By the same act, the benefits accruing to employees of the Federal Civil Works Administration were diminished. Compensation and death benefits were made payable only in event of disability or death from "traumatic injury while in the performance of duty," and only such medical services are to be rendered at government expense as are rendered necessary by "traumatic injury," defined by the act as "only injury by accident causing damage or harm to the physical structure of the body and shall not include a disease in any form except as it shall naturally result from the injury." There the matter now rests but with the gradual disbanding of the federal civil works corps the situation has become one of diminishing importance.

The same uniform consideration and cooperation reported above with respect to the National Recovery Administration has been manifested throughout all negotiations between representatives of the Association and the Federal Civil Works and Emergency Relief Administrations and the United States Employees' Compensation Commission, and their officers and employees.

HOSPITALIZATION OF VETERANS

All public laws granting medical and hospital treatment and domiciliary care to veterans (except veterans who served prior to the Spanish-American War) for injury or disease incurred or aggravated in the line of duty in the military or naval service were repealed by an Act to maintain the credit of the United States Government, approved March 20, 1933, sometimes referred to as the Economy Act. The clear intent of the act was to repeal also so much of those laws as authorized medical, surgical, nursing and hospital service for veterans suffering from diseases and injuries not of service origin, and it has been administered as thus construed. The same act, however, as amended by the Independent Offices Appropriation Act approved June 16, 1933, authorized the Administrator of Veterans' Affairs, under such limitations as the President might prescribe and within the limits of existing Veterans' Administration facilities to furnish to men discharged from the army, navy, marine corps or coast guard, for disabilities incurred in line of duty and to veterans of any war, including the Boxer Rebellion and the Philippine Insurrection domiciliary care when they are suffering from permanent disabilities, tuberculosis or neuropsychiatric ailments, and medical and hospital treatment for diseases or injuries.

By Executive Order, Veterans Regulation No. 6 (a), Eligibility for Domiciliary or Hospital Care, Including Medical Treatment, promulgated July 28, 1933, the President authorized the Administrator of Veterans' Affairs, within the limits of Veterans' Administration facilities, to furnish domiciliary or hospital care, including medical treatment, to honorably discharged veterans of any war, including the Boxer Rebellion and the Philippine Insurrection, in the following order of preference:

(a) To honorably discharged veterans of any war including the Boxer Rebellion and the Philippine Insurrection who are suffering with injuries or diseases which were incurred or aggravated in line of duty in the active military or naval service when in need of hospital treatment for such injuries or diseases.

(b) To persons honorably discharged from the United States Army, Navy Marine Corps or Coast Guard for disabilities incurred in line of

duty who are suffering with injuries or diseases which were incurred or aggravated in line of duty in the active military or naval service when in need of hospital treatment for such injuries or diseases

(c) To honorably discharged veterans of any war including the Boxer Rebellion and the Philippine Insurrection who served in the active military or naval service for a period of ninety days or more who are suffering with permanent disabilities or tuberculous or neuropsychiatric ailments which incapacitate them from earning a living and who have no adequate means of support

(d) To persons honorably discharged from the United States Army Navy Marine Corps or Coast Guard for disabilities incurred in line of duty who served in the active military or naval service for a period of ninety days or more who are suffering with permanent disabilities or tuberculous or neuropsychiatric ailments which incapacitate them from earning a living and who have no adequate means of support

By Executive Order, Veterans Regulation No 7 (a), Eligibility for Medical Care, promulgated July 28, 1933, the President authorized the Administrator of Veterans' Affairs, in his discretion, to furnish to honorably discharged veterans of any war, including the Boxer Rebellion and the Philippine Insurrection, and to men honorably discharged from the United States Army, Navy, Marine Corps and Coast Guard, suffering from disabilities incurred in the line of duty, such medical, surgical and dental services as might be found to be reasonably necessary for diseases or injuries incurred or aggravated in the line of duty in the active military or naval service

The law and regulations that have been cited limited hospital treatment to veterans suffering from diseases or injuries incurred or aggravated in line of duty in active military or naval service, and veterans without means of support and incapacitated from earning a living, suffering from permanent disabilities or tuberculous or neuropsychiatric ailments. Hospital and domiciliary care for non-service-connected temporary conditions were discontinued

That such a curtailment of the benefits previously granted to veterans suffering from injuries and diseases not of service origin would be accepted by all of the veterans organizations was too much to be expected. Approximately one hundred bills have been introduced in Congress proposing to restore some or all of the benefits withdrawn. In the Senate, bills of this character were referred to the Committee on Finance, and in the House of Representatives to the Committee on World War Veterans' Legislation, and there they remained without action. But on Jan 17, 1934, when the Independent Offices Appropriation Bill, H R 6663, had passed the House and was pending before the Senate Committee on Appropriations, Senator David A Reed of Pennsylvania offered an amendment to it to restore to the veterans, among other things, the hospital benefits of which they had been deprived. Senator Reed proposed

That any World War Veteran who was employed in the active military or naval service between April 6 1917 and November 11 1918 who was not dishonorably discharged suffering from disability disease or defect who is in need of hospitalization or domiciliary care and is unable to defray the necessary expenses therefor (including transportation to and from the Veterans Administration facility) may be furnished necessary hospitalization or domiciliary care (including transportation) in any Veterans Administration facility irrespective of whether the disability disease or defect was due to service. The statement of the applicant on such form as may be prescribed by the Administrator of Veterans Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses

The American Medical Association promptly filed a protest against the adoption of the proposed amendment

January 19, two days after Senator Reed filed his proposed amendment, the President promulgated Executive Order, Veterans Regulation No 6 (b) Eligibility for Domiciliary or Hospital Care, Including Medical Treatment authorizing hospital and domiciliary care and medical service beyond the limits laid down in Veterans Regulation No 6 (a). The new order extended such benefits to persons who between April 6 1917 and Nov 11, 1918, inclusive were provisionally in the military and naval service but who before being actually enrolled suffered injuries and diseases in the line of duty. Hospital and domiciliary care and medical service for veterans with non-service connected disabilities which had been limited to veterans suffering from permanent disabilities or tuberculous or neuropsychiatric ailments, were extended to include veterans suffering from such other conditions requiring emergency or extensive hospital treatment as might be prescribed by the Administrator of Veterans Affairs

Some members of the Senate Committee on Appropriations, to which the Reed amendment was referred, were of the opinion that it could not properly be reported as an amendment to the appropriation bill and therefore it was not so reported. When the bill came up for debate, however, Senator James F Byrnes of South Carolina offered an amendment authorizing substantially the same benefits as were authorized by Executive Order Veterans Regulation No 6 (b). Senator Frederick Steiwer of Oregon and Senator Pat McCarran of Nevada offered an amendment, which, so far as relates to hospital benefits, was adopted by the Senate in the following form

That any veteran of any war who was not dishonorably discharged suffering from disability disease or defect who is in need of hospitalization or domiciliary care and is unable to defray the necessary expenses therefor (including transportation to and from the Veterans Administration facility) shall be furnished necessary hospitalization or domiciliary care (including transportation) in any Veterans Administration facility within the limitations existing in such facilities irrespective of whether the disability disease or defect was due to service. The statement under oath of the applicant on such form as may be prescribed by the Administrator of Veterans Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses

The House of Representatives acquiesced in so much of the Steiwer-McCarran amendment as is set forth above, already adopted by the Senate, and the Independent Offices Appropriation Act containing this legislation, passed by both Houses, was vetoed by the President. It was then passed by the House of Representatives and Senate over the President's veto and is now a law. The hospitalization of veterans generally for non-service connected injuries and diseases is now governed primarily by the provisions of the Steiwer-McCarran amendment

CONTRACT SURGEONS OF THE SPANISH-AMERICAN WAR

In the scramble for benefits based on military service, one class of physicians, who served their country well in time of need, has been sadly neglected, namely, the contract surgeons who served during the Spanish-American War, the Philippine Insurrection and the Boxer Rebellion. Prior to March 20, 1933, they were entitled to pensions for injuries sustained in military service, just as all other veterans of those military activities were. But even then, contract surgeons did not share in the right given all other persons, even contract nurses, who served ninety days or more, to pensions for disabilities of a permanent character which incapacitated them for the performance of manual labor, regardless of the origin of such disabilities, and to pensions by reason of age alone, when they became 62 years old. The failure of the government to confer on contract surgeons benefits similar to those conferred on other participants in these military operations is difficult to explain and justify.

The discrimination against contract surgeons has become more acute since the passage of An Act to maintain the credit of the United States Government, approved March 20, 1933, commonly referred to as the Economy Act. The Economy Act repealed existing pension laws, with exceptions not here pertinent, and established a new deal for veterans. In this new deal, however, the contract surgeons of the Spanish-American War, the Philippine Insurrection and the Boxer Rebellion were again neglected. By an executive order issued by the President, March 31, 1933, Veterans' Regulation No 10, benefits conferred by other regulations on veterans of these military activities were limited to officers and enlisted men, "including those women who served as army nurses under contracts on or after April 21, 1898 and before August 13, 1898," with the exception that for the purposes of hospitalization the term "veteran of any war" was defined as including "persons who served overseas as contract surgeons of the Army on and after April 21, 1898, and before August 13, 1898." Pensions are now payable, therefore to officers and enlisted men and to contract nurses who served in the Spanish-American War, the Philippine Insurrection and the Boxer Rebellion for total permanent disabilities, but not to contract surgeons, because they are not officers enlisted men or contract nurses.

The failure of the contract surgeons who served during the Spanish-American War and the military expeditions that followed to obtain adequate recognition is probably due in large part to the fact that they were and are an unorganized group. To win recognition and benefits from Congress those who believe that they are justly entitled to such benefits must present their causes to their Senators and Representatives and

this is certainly best done through organized action. The exact number of contract surgeons who are now living is not known, but they number probably between four and five hundred. The Board of Trustees, Feb 19, 1932, authorized action looking toward the support of a movement to place these members of the medical profession on a parity, so far as pensions and other benefits are concerned, with the numerous lay persons who rendered similar service. But probably little can be accomplished unless the contract surgeons themselves organize and support such a movement more actively in the future than they have done in the past.

A bill to provide for the relief of contract veterans of the Spanish-American War including the Philippine Insurrection and the China Boxer Rebellion, was introduced in the Senate, S 1990, Jan 4, 1934 by Senator Charles L. McNary of Oregon, and in the House of Representatives H R 8580, March 10, 1934, by Representative Charles H. Martin of Oregon. The bill is identical in the two houses and undertakes to confer on contract surgeons and others of similar status the benefits of the Economy Act. It is hoped that in this way, or in some more effective way, justice can be done the contract surgeons of the Spanish-American War and the military expeditions that followed it.

LIBRARY OF THE SURGEON GENERAL'S OFFICE

The Library of the Surgeon General's Office is the largest medical library in the world. Its official designation, Library of the Surgeon General's Office, gives only a scant clue to its real character and purpose. "It is a national institution," says Surg Gen Robert U. Patterson in his annual report for 1933, "the material of which is available to the entire medical (including dental, veterinary, public health etc.) profession of the country." Surg Gen M. W. Ireland, now retired in testifying in support of the War Department appropriation bill for 1925, said of the Library: "It is a national library, and it is very unfortunate that during the Civil War when they started this library, they made it the library of the Surgeon General's Office because it has been looked upon as maybe a small concern by those people who are not acquainted with it."

In December 1933 the Library contained 905,000 books and pamphlets. During the fiscal year ended June 30 1933, 2,041 periodicals were received. During that year 5,282 readers made use of the library and 11,958 books were lent to 346 libraries and institutions throughout the country under the interlibrary system. Not the Medical Department of the Army alone but also the Bureau of Medicine and Surgery of the Navy, the United States Public Health Service, the Veterans' Administration and other branches of the federal government whose activities center in Washington have free recourse to this great center of medical knowledge.

Certainly these facts cannot have been recognized by the responsible officers of the War Department or by the director of the budget when they proposed to Congress a reduction in the annual appropriation for the library from \$19,500 to \$14,300. The annual appropriations for the library for each of the fiscal years 1925 and 1926 was \$20,000, and the amount appropriated annually since that time and up to and including the fiscal year 1934 has been \$19,500. With a record such as this and with the threatened advent of an era of high prices of all kinds, there can be no good reason for reducing by approximately one third the appropriation to this library.

The War Department appropriation bill carrying the appropriation for the Library of the Surgeon General's Office had been formulated in the War Department and passed by the director of the budget and was pending in the Committee on Appropriations, House of Representatives, before the proposed reduction in this appropriation came to the attention of the American Medical Association. The bill passed the House of Representatives, March 9, and at the present writing [March 15] is pending in the Senate. Whether anything can be done during the current year to check the deterioration in the library and in the library service that must result if such a reduction as is proposed is made in the appropriation for its maintenance is uncertain. Certainly, however, the medical profession of the country should unite in a continuing movement for the rescue and preservation of this potent instrumentality for the broader and better education of the physicians of the country.

FOOD, DRUG AND COSMETIC LEGISLATION

It came to the notice of the Association that the U. S. Department of Agriculture was preparing a revision of federal food and drug legislation, with a view to its enactment as a substitute for existing law in that field. Assistant Secretary of Agriculture Tugwell, who had the matter in charge was promptly informed that the resources of the American Medical Association were at his disposal for use in connection with this undertaking. They were never used, unless an invitation to the Association to be represented at a hearing on the proposed legislation can be so construed. The invitation was accepted. The hearing lasted two days but no copies of the contemplated legislation were available, and the discussion was of a more or less general character. On June 12, the bill prepared by the Department of Agriculture was introduced in the Senate by Senator Copeland as S 1944. This is the bill sometimes designated as the Tugwell bill. Later modifications of it, S 2000 and S 2800 have been variously referred to as the Tugwell-Copeland bill and as the Copeland bill.

The Tugwell bill was offered as a substitute for the Federal Food and Drugs Act of 1906, as amended, which it proposed to repeal. It proposed to extend the law so as to cover cosmetics and to cover advertising relating to foods, drugs and cosmetics. Drastic administrative provisions in it aroused a storm of protest and are largely responsible, it is believed, for the widespread bitter opposition that still prevails against all legislation in this field except such as has been prepared by food, drug, cosmetic and advertising interests and introduced on their behalf. On June 14, 1933 the Board of Trustees after a careful study of the Tugwell bill, adopted the following resolution:

WHEREAS The American Medical Association has for years protested against the inadequacy of the National Food and Drugs Act of 1906 because of which inadequacy the officers of the government charged with the enforcement of the act have been and are unable effectively to protect the people against fraud and danger to health be it

Resolved That the American Medical Association pledges its support toward procuring the formulation and enactment of effective national food and drug legislation adequate for the protection of the people

The Senate Committee on Commerce, to which the Tugwell bill had been referred, referred it to a subcommittee, of which Senator Royal S. Copeland of New York is chairman. That subcommittee held hearings in Washington December 7 and 8. The Association took no part in those hearings but was represented by an observer. After the hearing, however, a representative of the Association pointed out to Senator Copeland some of the provisions of the bill that seemed inexpedient. Senator Copeland, January 4, introduced a revised bill, S 2000. Later, February 19, a second revision was introduced, S 2800. S 2800 was made the subject of a hearing before the full Senate Committee on Commerce, February 27 to March 3, when a representative of the Association discussed the bill, commending it for its good features and pointing out changes that seemed to be needed to make it a more effective measure. Subsequently an exhaustive brief of the same tenor was filed.

As this report is being written (March 15) the Copeland bill, S 2800, has been reported to the Senate and is now on the calendar. Four other food, drug and cosmetic bills before this committee may therefore be considered as dead. Five similar bills are pending before the Committee on Interstate and Foreign Commerce, House of Representatives.

FEDERAL CONTROL OF MEDICINAL LIQUOR

On Dec 5, 1933, the twenty-first amendment to the constitution of the United States became effective, and direct federal control of the medicinal use of liquor passed back to the states. The determination of the nature and extent of the control that is to be exercised is now a matter primarily for state associations. The resources of the Association as a whole are at the command of the state associations to aid them in the discharge of this function.

BIRTH CONTROL

A bill to facilitate the dissemination of information concerning the prevention of conception and of preparations and devices to accomplish that end was introduced in the Senate, June 6 1933, by Senator Daniel O. Hastings of Delaware S 1842 and in the House of Representatives June 8, 1933, by Representative

Walter M Pierce of Oregon, H R 5978 Hearings were held on these bills The American Medical Association was not represented at either of these hearings and did not participate in them

REGULATION OF RADIO BROADCASTING

A bill, S 2660 to regulate broadcasting from a studio in the United States through a broadcasting station in a foreign country back into the United States has passed the Senate It has been favorably reported in the House of Representatives and is now on the calendar This bill is designed to prevent broadcasting from the United States by remote control, through a foreign country and back into the United States matter that could not be broadcast from a United States broadcasting station directly throughout the United States in the first instance

STATE LEGISLATION

During 1933, the legislatures of forty-three states met in regular session and in addition forty two special sessions were held Since Jan 1, 1934, to date (March 15) the legislatures of nine states have convened in regular session and special sessions have convened in four other states All bills of medical interest introduced in these sessions were studied and appropriate notices were sent to the interested state medical associations Advanced notices were sent, too, to the presidents and secretaries and the chairmen of the legislative committees of the several state associations, concerning bills in which they had particular interests Abstracts of bills were published in THE JOURNAL, and later their progress was reported A survey of all state legislation considered in these legislative sessions, of interest to the profession was published in the November and December issues of the AMERICAN MEDICAL ASSOCIATION BULLETIN

The uniform narcotic drug act was enacted in 1933 in Florida, Nevada, New Jersey and New York, and in 1934 in Virginia, with slight modifications in some states In 1933 basic science laws were enacted in Arizona and Oregon So-called medical lien bills were enacted in 1933 in Arkansas, Indiana, Minnesota and Texas and in 1934 in Iowa The cults scored heavily against public health interests in 1933 Independent chiropractic examining and licensing boards were created for the first time in Colorado and Michigan, and the chiropractic acts in Montana, New Mexico, North Carolina and North Dakota were amended so as to enlarge the scope of chiropractic practice Osteopaths were granted enlarged rights in New Mexico and North Dakota, and but for the courageous and intelligent use of the veto power they would have been granted unlimited rights in Michigan A naturopathic practice act conferring on naturopaths an independent status would now be a law in Arizona but for the governor's veto Why cult legislation of this character should be so successful is a question calling for searching inquiry by state organizations

MISCELLANEOUS SERVICES

The Bureau of Legal Medicine and Legislation has throughout the year cooperated actively with state and county medical associations in their efforts to solve their legislative and medico-legal problems Advice to individual correspondents concerning matters of law have necessarily been of a general character for it is impossible for the Association to undertake to solve the personal legal problems of its Fellows and members Where information has been asked concerning matters of a strictly medicolegal type citations and information have been freely furnished The Bureau has continued as heretofore to prepare abstracts of current court decisions for publication in THE JOURNAL

Bureau of Health and Public Instruction

The work of the Bureau has included editing of the Question and Answer Department in HYGIEIA maintenance of a radio program in Chicago furnishing radio talks to medical societies for local programs outside Chicago information exchange service to state and county medical societies in their educational activities preparation of material relating to protection of medical research representing the American Medical Association on advisory boards of lay organizations personal appearances on invitation in various parts of the United States and writing of articles for publication

RADIO

The American Medical Association maintained a weekly broadcast of two five-minute talks and one fifteen-minute talk over station WBBM, Chicago, through 1933 In December an arrangement was perfected for broadcasting a weekly talk over a coast-to-coast network of the National Broadcasting Company the talks on the network being divided about equally between the editor of THE JOURNAL and the director of the Bureau During the current year broadcasting facilities have been made available by the Columbia Broadcasting System Thus the service of the two great national radio organizations, generously provided, is being utilized for the dissemination of information to the people of the country Cooperation was extended to radio programs of reputable organizations in Chicago Radio talks furnished to local medical societies have been mentioned

The Bureau prepared or edited 193 radio talks, of which 168 were broadcast over Chicago stations in the name of the American Medical Association, while 25 were not broadcast locally, 171 such talks were prepared in 1932 The total of available talks now closely approaches 500 State, district and county medical societies, and other organizations cooperating with such societies received 7,277 copies of radio talks for use in local broadcasts, as compared with 4,312 in 1932

SERVICE TO STATE AND COUNTY SOCIETIES

The Bureau attempts to function as a clearing house of information on public health and health education, for state and county medical societies Educational material is furnished such societies as well as individual physicians in close cooperation with HYGIEIA using especially the HYGIEIA clip sheet and collections made of HYGIEIA clippings on more than seventy topics of common interest

PROTECTION OF MEDICAL RESEARCH

As in previous years, the Bureau has cooperated closely with the American Medical Association Committee for the Protection of Research

COOPERATION WITH LAY ORGANIZATIONS

By order of the Board of Trustees the director is acting as representative of the American Medical Association on medical advisory committees for the following organizations

The National Congress of Parents and Teachers has had the cooperation of the American Medical Association for several years through the donation by HYGIEIA of half the necessary blanks for the summer round up of preschool children During 1933 the advisory committee for the summer round up met once to consider printed matter for use in the 1935 round up This consisted principally of examination blanks, instructions for state and local leaders and leaflets for parents explaining the purposes of the summer round up The instructions and the leaflets for parents will emphasize the desirability of having the children examined whenever possible in the offices of their family physicians

The General Federation of Women's Clubs invited the American Medical Association in 1933 to appoint a representative to the medical advisory board for the federation's department of health and welfare The director of the Bureau was appointed and instructed to ask for the appointment of two other physicians preferably practicing physicians as additional representatives Dr N B Van Etten of New York and Dr A C Christie of Washington were appointed in response to this request Two meetings were held in 1933 the first attended by the director only the other by all the representatives of the American Medical Association The result of deliberations at these meetings was briefly as follows A proposed study of medical economies by local women's clubs was not undertaken a proposal to endorse group hospitalization plans in principle was postponed an outline for studies by local women's clubs of the public health work in their respective communities was approved for publication after extensive changes suggested by the American Medical Association representatives had been made an outline of principles for child health and welfare activities was criticized by the director of the Bureau and many but not all the changes suggested by him were made a conservative program of cancer

education in cooperation with the American Society for the Control of Cancer was endorsed.

The National Committee for Boys and Girls Club Work, better known as the 4-H Club movement, also requested a representative from the American Medical Association during 1933, and the director of the Bureau was named. He addressed the committee and a group of its state club leaders at the annual congress in Chicago in December and visited a state meeting at Lafayette, Ind., earlier in the year, he also attended some conferences with the Elizabeth McCormick Fund staff relating to examination forms and procedures. He contended for a more constructive procedure in the health phase of the committee's activities than the contest in which so called healthiest boys and girls are selected from local groups, state-wide groups and finally a nationally selected group. Results of his efforts, if any, were not apparent. The movement reaches almost a million boys and girls in rural areas. Further efforts to aid this committee in developing its health program may prove fruitful.

The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association met at Minneapolis in February 1933 and considered a number of reports dealing with health problems in the schools. One report, dealing with inspection of school children by teachers or nurses in the absence of available medical service, was published.

PERSONAL APPEARANCES

The director of the Bureau made addresses on invitation before six medical society or auxiliary groups, one medical school class, two educational groups, four public health groups and five lay groups, and attended nine meetings of advisory conferences.

ARTICLES PUBLISHED

Articles by the director of the Bureau were published in the AMERICAN MEDICAL ASSOCIATION BULLETIN, a state medical journal and a county society bulletin, two education magazines, a magazine of general circulation to the public, and in transactions of the annual meetings of the National Education Association and the National Tuberculosis Association. Contributions were published also in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and in HYGEIA.

EXHIBITS

The Bureau cooperated with the American Medical Association Bureau of Exhibits in preparing exhibits for various meetings and for A Century of Progress.

PAMPHLETS

Pamphlets have been extensively revised. A new series on sex education was prepared and published, a second printing was required before the end of the year. Nine other standard pamphlets were revised and brought up to date, twenty-two new titles added to the lay catalogue and ten old ones dropped.

A CENTURY OF PROGRESS

The specific contribution of this bureau to A Century of Progress was a set of 145 questions on health, together with answers thereto carefully revised and checked by a group of practicing physicians. These were displayed in visible file units which made them readily accessible to visitors at the American Medical Association exhibit. They were constantly in demand. They have been republished in booklet form for use as a HYGEIA premium.

There was no change in the personnel of the Bureau during the year. The work done is measured, to some extent, by the volume of correspondence. Letters written on Bureau business numbered 3,164, as compared with 2,824 in 1932. Letters written in reply to questions received by HYGEIA totaled 4,612, as compared with 3,569 in 1932.

Bureau of Investigation

Physicians and laymen continue to call on the Bureau of Investigation for information on the subjects with which the Bureau deals. Of the nearly 11,000 inquiries that were received and answered by the Bureau during 1933, the letters were about evenly divided between laymen and physicians. Two things have stimulated interest on the part of the public and the profession in the matter of "patent medicines." One is the proposed new

law that will extend the powers of the national government over the sale and particularly the advertising of nostrums. The other is the fact that there is probably more misleading or fraudulent "patent medicine" advertising today than there has been in the past quarter-century. While the newspapers of the country, as a result of the economic situation, have in many instances let down the bars to much "patent medicine" advertising that in more prosperous times they would reject, they have nevertheless kept such advertising within certain bounds and have certain standards of advertising decency. Some radio stations, however, have developed no such ethical conscience, and much of the "patent medicine" advertising that goes over the air is reminiscent of the type used by nostrum exploiters before the passage of the National Food and Drugs Act of 1906. Such blatant quackery has aroused the medical profession and even the more intelligent part of the lay public to the need of an extension of the powers of the Food and Drugs Act to cover collateral advertising instead of, as now, merely the advertising that appears on or in the trade package. This has resulted in the Bureau of Investigation's receiving thousands of inquiries for information about "patent medicines" that are advertised over the radio, and for information, also, as to whether the proposed new law will help to put an end to what has become a stench in the nostrils of decent people.

The Bureau of Investigation continues to cooperate with the Better Business Bureaus, both local and national. Not only the National Better Business Bureau but practically all the component branches located in cities all over the United States receive each week from the Bureau of Investigation pages from THE JOURNAL carrying articles prepared by the director of the Bureau that deal with any phase of the nostrum evil or quackery with which advertising men might properly be concerned.

The Bureau has also received an unusual number of inquiries from professors and teachers in universities, colleges, normal schools and high schools, who seek information on "patent medicines." As a result of this interest, the Bureau also gets a large number of inquiries from the students of such institutions.

The director of the Bureau has prepared the usual number of articles on "patent medicines," quacks and medical schemes of a dubious character that have been published in practically every issue of THE JOURNAL the past year. While most of the material represents individual investigation by the Bureau, with, of course, the aid of such analytic work as the Chemical Laboratory was asked to furnish, there have also been a number of articles based on reports issued by such agencies as the Post Office Department, the Federal Trade Commission and the Food and Drug Administration.

The director of the Bureau has been called on to give a number of talks, usually illustrated with lantern slides, on either "patent medicines" or cosmetics. Not all of these requests could be complied with without impairing the efficiency of the Bureau. Thirty-three such talks were however, given, of which fifteen were in Chicago or the Chicago area and the remainder divided among seven states. All these talks were before public audiences and most of them were given under the auspices of either state or county medical societies or the woman's auxiliaries of the state or county organizations.

The various pamphlets on quackery and the nostrum evil are still in demand. At the beginning of the year the American Society for the Control of Cancer asked the director of the Bureau to prepare a new pamphlet on quack cancer cures and treatments so that they could distribute numbers of these pamphlets at the society's exhibit at the Century of Progress exposition. The pamphlet was prepared and made available by the time the exposition opened.

There has been an unusually brisk demand for the pamphlet on cosmetics, owing to the interest that has been stimulated by several deplorable accidents in the use of certain of these products. There has been an especially insistent demand for a third volume of "Nostrums and Quackery." The first volume of this book was issued in 1912 and has been out of print for some years. The second volume which is still available, was issued in 1921. There is already available plenty of material for volume 3, but the routine work of the Bureau has absorbed all the available time and so far has made it impossible to get out the third volume.

The lantern slides prepared by the Bureau are still being called for by physicians or public health officials who wish to give talks on the subject with which they deal. An extension of this service is now in process of development. The same is true of the educational posters. Three of the posters that were prepared by the Bureau of Investigation a few years ago on vitamins, food iron and food calcium have been discontinued, as similar posters are available without cost. The latter have been prepared by the National Live Stock and Meat Board and approved by the Committee on Foods of the Association.

Bureau of Exhibits

The activities of the Bureau of Exhibits are carried on along several lines—the Scientific Exhibit each year, the Central Scientific Exhibit, and Association exhibits.

THE ANNUAL SCIENTIFIC EXHIBIT

The Milwaukee Session marked the thirty-fifth year for the Scientific Exhibit. Twelve sections of the Scientific Assembly were again represented by official committees, under whose direction groups of exhibits in the different specialties of medicine were made. There was a total of 120 exhibits, the same number as at New Orleans, but the hall was considerably larger, making it possible to provide more room in which the exhibits could be shown and more aisle space in which the visitors could circulate. Thirty-seven papers read before the sections of the Scientific Assembly were illustrated in the Scientific Exhibit. There were thirty-nine motion pictures shown in the different booths and in the motion picture programs sponsored by several section exhibit committees. Four special exhibits, put on by special committees appointed for the purpose included poliomyelitis and cancer, both shown for the second time, fresh pathology, which had been omitted at New Orleans, and a new exhibit on circulation of the blood in the capillaries.

The Committee on Awards worked faithfully for three days the task of selecting the most commendable exhibits being a difficult one because of the diversified nature of the material shown.

THE CENTRAL SCIENTIFIC EXHIBIT

No exhibits from the Milwaukee Session were selected for the Central Scientific Exhibit. Part of the exhibit space at the headquarters building is being used for offices, and promotion of this activity has ceased for the time being.

ASSOCIATION EXHIBITS

Under the heading Association Exhibits are conducted activities falling into two groups. The first includes exhibits of a strictly scientific nature dealing with the work of the American Medical Association and shown at medical and other professional meetings. The second consists of exhibits for the public and supplements the program of the Bureau of Health and Public Instruction. Such exhibits, shown at fairs, exposition school gatherings and the like, are put on with the co-operation or approval of the state or county medical society in that territory.

During the year 1933 many requests for exhibit material could not be complied with because of the pressure of work connected with the exhibit of the American Medical Association at A Century of Progress Exposition. Thirty-two exhibits were sent out, thirteen to professional groups and nineteen to lay groups. This does not include the exhibits of five bureaus and councils of the Association at the Milwaukee session or the exhibit at A Century of Progress Exposition.

EXHIBIT AT A CENTURY OF PROGRESS EXPOSITION

During the five and a half months of A Century of Progress Exposition, nearly five million people visited the exhibit of the American Medical Association. It was impossible to furnish demonstrators to talk to groups as they passed through the information being imparted by photograph records carefully worded labels and mechanical apparatus. A list of 145 questions and answers which had appeared in *HYGEIA* was extremely popular. Attendants were present to make note of additional questions which the visitors asked and these were turned over to the Bureau of Health and Public Instruction for reply by mail.

Committee on Foods

The Committee on Foods added to its membership and made excellent progress during 1933. Dr Edwin O. Jordan, Ph.D., Sc.D., professor of bacteriology at the University of Chicago, Dr James S. McLester, M.D., professor of medicine, University of Alabama School of Medicine, and Dr Mary Swartz Rose, Ph.D., professor of nutrition, Teachers College, Columbia University, became members of this body through appointment by the Board of Trustees.

The submission of foods to the Committee has continued at approximately the same rate as during the preceding two years—roughly, 600 per annum. Applications for consideration of simple types of foods, such as breads and flours were refused for six months to permit the Committee to catch up on pending work. The Committee declined to pass on alcoholic beverages. Owing to the volume of work, a considerable number of satisfactory submissions have not been acted on, many incomplete or unsatisfactory submissions have not been developed. Requests for outline of procedure for submitting foods number in the hundreds. The rigid requirements for submitting foods and governing accepted foods unquestionably have prevented submissions from running over the thousand mark each year.

Products submitted, accepted and rejected and acceptances withdrawn are summarized in the following table.

Report of Committee's Actions

Products submitted—total up to Dec 31 1933	1 860
1932	632
1933	583
Products accepted—total up to Dec 31 1933	1 276
1932	493
1933	490
Products rejected—total up to Dec 31 1933	61
1932	16
1933	41
Withdrawals of acceptance—total (1933)	31

RULES AND REGULATIONS

The Rules and Regulations have been almost wholly revised and republished. The new rules state more precisely the purpose and policy of the Committee, the significance of acceptance and of the seal, the conditions of acceptance, the aims of the Committee for cooperation with the food and advertising trade, and the procedure of submitting foods. The most important amendment calls for the regular submission of all advertising subsequent to acceptance, to assure that the advertising is maintained acceptable and as a safeguard to the significance of the seal and of acceptance. Although this requirement adds to the routine burden of the office of the Committee, it is an essential step to assure that the prestige and standing of the Committee shall not be endangered by faulty advertising for accepted foods. The established standards are being rigidly upheld.

It is expected that the Rules and Regulations will require little amendment in the future. They declare in certain and definite terms the purpose and scope of the operations of the Committee as a public health and welfare body of the American Medical Association. They lay down the general rules and basic principles governing accepted foods. Good food advertising and proper foods depend on the response and efforts of the trade to meet the standard of these requirements. Constant requests for the Rules indicate that they are being recognized.

GENERAL COMMITTEE DECISIONS

The Committee has adopted twenty new or revised General Committee Decisions. These decisions define the position of the Committee on certain advertising, food composition and public health issues. As the work develops more and more attention is being given to questions of special and direct concern to public health. This is evidenced by such decisions as 'Addition of Phenolphthalein, Acetylsalicylic Acid (Aspirin) and Other Drugs to Chewing Gum Candy and Food Articles', 'Contamination of Fruits and Vegetables with Toxic Insecticide Spray Material', 'Tolerance for Arsenic, Copper and Lead in Foods and Pasteurization of Milk'. Numerous requests—especially by the trade—are made for copies of these decisions. They are being recognized by sponsors of accepted foods as well as by those apparently not interested in gaining acceptance for their products.

The General Committee Decisions adopted or revised during 1933 are listed herewith

I Decisions Governing Advertising

Academic Titles Doctor and M.D. as Integral Parts of Names of Foods (revised)
The Designations Food Concentrate and Scientific Food Concentrate for Foods
The Claim Digests Starch for Foods Containing Dextrically Active Malt or Malt Extract
Educational Food Advertising
Good Food Advertising
Health Food Claims and the Term Healthful (revised)
The Ideal Label for Foods
Mineral, Spring, Natural or Alkaline Waters
Questionnaire Advertising
Resistance Claims in Food Advertising
So Called Special Diabetic Foods or Special Foods for Sugar and Carbohydrate Restricted Diets
Trick Claims in Food Advertising
Vague Clinical Experience Claims

II Decisions Governing Food Composition

Fortification of Foods Other Than Table Salt with Iodine or Iodine Compounds
Iodized Salt and Cauter in Iodine Deficiency Disease (revised)
Whole Wheat and Graham Foods

III Special Public Health Decisions

Addition of Phenolphthalein, Acetylsalicylic Acid (Aspirin) and Other Drugs to Chewing Gum Candy and Food Articles
Contamination of Fruits and Vegetables with Toxic Insecticide Spray Material
The Pasteurization of Milk
Tolerances for Arsenic, Copper and Lead in Foods

Of special interest have been efforts of the trade to merchandise foods with enhanced nutritional values. A considerable number of vitamin D liquid milks and one vitamin D evaporated milk have been accepted. Several nationally distributed vitamin D evaporated milks are about to be accepted. The Committee is requiring that all these milks be proved nutritive by chemical evidence. To all appearances vitamin D milk soon will be generally distributed. A few vitamin D fortified breads, cereals and other foods are already established on the market. Special vitamin B foods also are receiving attention. These are prepared by the addition of substantial quantities of wheat germ or rice bran, by-products of the milling industry, rich in vitamin B and heretofore used for animal feed. Other special vitamin-fortified foods planned for the market are in the offing.

The manufacture of foods with enhanced values for improving the nutrition of the public is a commendable commercial enterprise. It is important, however, that such undertakings have authoritative, commercially disinterested guidance. The policy of the Committee on these issues is based solely on public welfare and established knowledge.

The food and advertising trades are quick to exploit newly reported nutritional observations before they are adequately substantiated. Results of limited animal or clinical studies are given exaggerated unwarranted significance. The urge to reap gain from an uninformed public on the basis of unripe knowledge requires constant, firm and understanding control. The Committee exerts a positive influence for restraining impetuous sales projects by the trade in the still speculative field of the newer knowledge of nutrition.

Reports on a number of scientific or pseudoscientific investigations sponsored by the advertising trade were submitted and passed on during the year.

The Committee is constantly challenged by complex and difficult problems of almost every conceivable character involving food composition, nutrition, physiologic effects of foods, relation of foods to public health, proper labels and advertising claims, manufacturing methods, and so on. The members of the Committee have conscientiously given of their time, knowledge and experience to the good of the public. They have displayed a sympathetic understanding toward the public spirited members of the trade and have cooperated wholeheartedly to help them when possible. It is the essential purpose of the Committee to aid the food industries to attain newer and higher planes of merchandising and thereby better serve public welfare. The trade is by no means unappreciative. The many letters of gratitude and commendation from the trade show that it recognizes the spirit of the Committee and is gladly willing to carry through with it to the ultimate goal. The splendid support of the trade is an honor.

The office work of the Committee has steadily increased. The office personnel and system have been reorganized to meet the exigencies of the new demands. Members of the trade appear daily for consultation and interview. The expanding volume of correspondence with physicians indicates their growing interest in the Committee. General correspondence is especially heavy, requests come in from all quarters for information on almost every subject in the field of foods and nutrition. Contacts with food manufacturers by letter and interview indicate beyond question that the influence of the Committee is rapidly extending and becoming increasingly recognized. A number of sections for the book "Accepted Foods" were prepared, but pressure of other work prevented completion of more than possibly one fourth of the material. The office follows up all requirements of the Committee for accepted products to insure compliance by their sponsors. This involves much routine work but is a necessary part of the thoroughness with which the work is being carried on. With few exceptions the trade is thoroughly and wholeheartedly cooperative. Expressions of commendation are many and of criticism few.

Commencing last October, a series of monthly articles on the work of the Committee entitled "A Housewife Looks at the Committee on Foods" has appeared in *Hygeia*. Each article is devoted to an individual type of foods, permissible and improper claims, requirements of composition for acceptance, pertinent Committee decisions and actions, and general information on the work of the Committee. A radio talk on the Committee also was given each month.

The Committee is undertaking a form of social research in the field of foods and food advertising. It is developing a new and enlarged concept of the nutritional values of merchandised foods and of the scope and character of food advertising in the interest of public welfare and health. It is defining the principles that should govern food composition and advertising. These principles, once defined, become diffused through the food and advertising trades and will become the recognized codes of food merchandising and advertising of the future. The food industry is recognizing these principles laid down by the Committee and putting them in practice.

Donations for Pershing Memorial Returned to Donors

Since only a little more than one fourth of the sum required was subscribed to the fund for the establishment of a memorial room in the Pershing Memorial in Paris, and because it was not thought to be advisable to ask for additional subscriptions, all donations were returned to the individual donors and groups concerned.

Field Secretary

The Board of Trustees has given most careful consideration to the proposal that a Field Secretary should be employed and has concluded that it is not advisable to take final action in this matter at the present time. There is grave doubt that results that might be realized through the activities of any individual employed for the indicated purposes would justify the expense involved. Not more than a small part of the field could be covered in any one year. Prolonged absences would make it difficult if not impossible, for the person so employed to keep fully informed concerning developments in the home offices. During the last three years it has been possible to maintain closer contacts with constituent and component societies, and in the year covered by this report the field work of official representatives has been of far larger scope than ever before. More state county and district societies have been visited and the number of appearances of official representatives of the Association before lay audiences has been greater than in any previous year.

The President, the President-Elect, members of official bodies and the heads of practically all the departments at Association headquarters have appeared before an unusually large number of state district and county societies during the last year and have also participated in the programs of numerous civic and social organizations.

During the year the editor of *THE JOURNAL* delivered approximately 125 addresses in various parts of the United States which dealt with various subjects of important interest to the profession and to the lay public. The director of the

Bureau of Medical Economics spent 122 days in field investigations, during which time he appeared before the state or county medical associations in eighteen states and in twenty cities. The director of the Bureau of Health and Public Instruction, the director of the Bureau of Investigation, the secretary of the Council on Pharmacy and Chemistry, the secretary of the Council on Medical Education and Hospitals and other department heads attended numerous meetings of professional and lay organizations held in practically all parts of the country. The Secretary of the Association visited twelve states and appeared on the programs of state medical associations in most of these states and on the programs of county and district medical societies in practically all of them. Most of the states were visited during the year by official representatives of the Association.

Employees

The total number of employees on April 1, 1934, was 526. The largest number of employees at any one time in 1933 was 512. The number employed at the time this report was prepared was 544. Variations occur because of requirements dependent on the amount of work to be done at certain intervals. The reduction in working hours effected by the National Recovery Act and the growing demands made on the Association have compelled the employment of additional personnel in some departments.

The Board of Trustees desires to record its appreciation of the loyal and efficient service of the Association's employees.

Respectfully submitted

J. H. J. UPHAM, Chairman
AUSTIN A. HAYDEN, Secretary
ARTHUR W. BOOTH
D. CHESTER BROWN
ALLEN H. BUNCE
THOMAS S. CULLEN
JOSEPH A. PETTIT
ROCK SLESTER
C. B. WRIGHT

ADDENDA TO REPORT OF BOARD OF TRUSTEES

COMMITTEE ON THERAPEUTIC RESEARCH

The Committee on Therapeutic Research, a standing committee of the Council, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research.

During the year 1933 the committee made twenty-three new grants. A detailed list of these grants together with a list of publications during 1933 and of unexpired grants made before Jan. 1, 1933, is appended.

The following is a list of the investigations conducted with the assistance of grants made by the Therapeutic Research Committee, reports of which were published during 1933.

1. Studies on Respiration with Action Potential Methods—Robert Gesell *American Journal of Physiology* 105: 37-38 (July) 1933.
2. Researches on Nitrogenous Glycosides. II. The Synthesis of Glycosido Ureides. Katherine M. Haring and Treat B. Johnson *Journal of the American Chemical Society* 55: 395 (Jan.) 1933.
3. A Study of the Metabolic Activity of the Pancreas. Eugene I. Still, A. L. Bennett and V. B. Scott. *American Journal of Physiology* 106: 509 (Dec.) 1933.
4. The Absorption of Insulin from the Gastrointestinal Tract. I. The Effect of Calcium Lactate, Sodium Bicarbonate and Blood Serum in Pancreatized Dogs. A. G. Eaton and John R. Murlin. *American Journal of Physiology* 104: 636 (June) 1933.
5. Serum Sickness in Rabbits. IV. Influence of Various Sera upon the Occurrence of Serum Sickness. Moyer S. Fleisher and Lloyd Jones. *Journal of Immunology* 24: 369 (May) 1933.
6. Serum Sickness in Rabbits. V. Immediate and Accelerated Reactions. Moyer S. Fleisher and Lloyd Jones. *Journal of Immunology* 24: 383 (May) 1933.
7. The Relation of Serum Frictions to Serum Sickness in Rabbit. Moyer S. Fleisher and Lloyd Jones. *Proceedings of the Society for Experimental Biology and Medicine* 30: 1195 (June) 1933.
8. Protein as a Stimulant for Secretion of Pepsin in George R. Cowgill and Elizabeth R. B. Smith. *Proceedings of the Society for Experimental Biology and Medicine* 30: 1228 (June) 1933.
9. Meat Extracts as Stimulants for Secretion of Pepsin in Elizabeth R. B. Smith and George R. Cowgill. *Proceedings of the Society for Experimental Biology and Medicine* 30: 1284 (June) 1933.
10. Proteins as Stimulants for the Secretion of Pepsin. Elizabeth R. B. Smith and George R. Cowgill. *American Journal of Physiology* 105: 19 (Sept.) 1933.

11. Clinical Manifestations of Hypo and Hypermagnesaemia. Arthur D. Hirschfelder. *Journal of Clinical Investigation* 12: 982 (Sept.) 1933.
12. A Rapid Method for Determining Magnesium in Blood and Urine. Arthur D. Hirschfelder. *Journal of Clinical Investigation* 11: 841 (July) 1933.
13. Clinical Manifestations of Variations in Blood Magnesium—Hypo magnesaemia and Hypermagnesaemia. Arthur D. Hirschfelder. *Proceedings of the Society for Experimental Biology and Medicine* 30: 996 (April) 1933.
14. Clinical Effects of High and Low Blood Magnesium and of Renal Insufficiency on the Action of Soporific Drugs. Arthur D. Hirschfelder. *Journal of Pharmacology and Experimental Therapeutics* 48: 277 (July) 1933.
15. A Comparative Study of the Antidotal Action of Picrotoxin, Strychnine and Cocaine in Acute Intoxication by the Barbiturates. A. H. Maloney. *Journal of Pharmacology and Experimental Therapeutics* 49: 133 (Oct.) 1933.
16. Mercurial Inunctions in the Treatment of Syphilis. H. N. Cole, H. F. de Wolf, N. E. Schreiber, T. Sollmann and Joseph Van Clive. *Archives of Dermatology and Syphilology* 27: 111 (Jan.) 1933.

During 1933 the following grants were made:

- Grant 196. Arthur D. Hirschfelder, professor of pharmacology, University of Minnesota School of Medicine, \$250 to investigate the concentration of calcium and of magnesium in the blood in experimental and clinical conditions.
- Grant 197. Fred E. D. Amour, Department of Chemistry, University of Denver College of Liberal Arts, \$150 to investigate the effects of Provokol and related compounds.
- Grant 198. Roy R. Kracke, chairman of the Department and Associate Professor of Pathology, Emory University School of Medicine, \$250 to investigate bone marrow stimulation.
- Grant 199. Henry G. Barbour, associate professor of pharmacology and toxicology, Sterling Hall of Medicine, Yale University, \$250 to investigate the effects of metabolism and water exchange of long continued administration of morphine.
- Grant 200. Walter Bauer, Massachusetts General Hospital, the Robert W. Lovett Memorial Foundation of the Harvard Medical School, \$250 to investigate the anatomy and physiology of normal joints with special reference to rheumatoid arthritis.
- Grant 201. George R. Cowgill, associate professor of physiologic chemistry, Sterling Hall of Medicine, Yale University, \$250 to investigate vitamin B in relation to morphine addiction.
- Grant 202. Charles M. Gruher, professor of pharmacology, Jefferson Medical College of Philadelphia, \$200 to investigate the effects of drugs on Bell's muscle, trigon and fundus of the urinary bladder and of Dilaudid on the intestine of unanesthetized dogs.
- Grant 203. Louis N. Katz, physiologist and director of cardiovascular research, Nelson Morris Memorial Institute for Medical Research, Michael Reese Hospital, Chicago, \$250 to investigate the action of drugs on the coronary circulation.
- Grant 204. E. B. Krumhaar, professor of pathology, McManes Laboratory of Pathology, University of Pennsylvania School of Medicine, \$100 to investigate leukocyte attraction.
- Grant 205. J. T. McClendon, professor of physiologic chemistry, University of Minnesota Medical School, \$200 to investigate the relation of iodine to goiter.
- Grant 206. James H. Means, Massachusetts General Hospital, \$250 to investigate the effects of liver extracts on hematopoiesis in human subjects with pernicious anemia and in guinea pigs.
- Grant 207. Valy Meakin, department of pathology, Harvard Medical School, \$200 to investigate inflammation and tuberculosis in relation to immunity.
- Grant 208. John R. Murlin, director and professor of physiology, Department of Vital Economics, University of Rochester School of Medicine, \$150 to investigate the absorption of insulin from the alimentary tract.
- Grant 209. V. C. Myers, professor of biochemistry and T. C. Bing, Department of Biochemistry, Western Reserve University School of Medicine, \$250 to investigate iron metabolism.
- Grant 210. C. I. Reed, associate professor of physiology, University of Illinois College of Medicine, \$200 to investigate the use of viosterol 10,000 X in seasonal hay fever.
- Grant 211. Samuel R. M. Reynolds, Department of Physiology and Pharmacology, Long Island College of Medicine, \$150 to investigate the identification and standardization of Progesterin.
- Grant 212. William C. Rose, professor of physiologic chemistry, University of Illinois, \$375 to investigate the isolation of an unknown dietary essential present in proteins.
- Grant 213. Richard W. Whitehead, professor of physiology and pharmacology, University of Colorado School of Medicine and Hospitals, \$200 to investigate the influence of suprarenal cortex extract administration on the resistance to bacterial toxins.
- Grant 214. F. A. Park, professor of pediatrics and J. A. Pierce, Johns Hopkins University School of Medicine, \$200 to investigate the reaction of cartilage.
- Grant 215. William R. Amberson, professor of physiology, University of Tennessee College of Medicine, \$250 to investigate hemoglobin per fusion fluids.
- Grant 216. A. H. Maloney, head of the department and professor of pharmacology, Howard University School of Medicine, \$200 to investigate picrotoxin and coriamyrtin-barbiturate antagonism and dehydration and convulsant action of drugs.
- Grant 217. Henry B. Richard, professor of medicine, Cornell University Medical College, \$250 to investigate ex-hormone therapy.
- Grant 218. O. W. Barlow, assistant professor of pharmacology, Western Reserve University School of Medicine, \$150 to investigate the effects of a series of analeptics against pentobarbital, tribromethanol and chloral hydrate.

The following grants were issued before Jan 1, 1933. In some cases the grant has expired and an unexpended balance remains, or the work is not yet completed, or not yet published.

Grant 102 C W Greene, professor of physiology and pharmacology, University of Missouri Department of Physiology \$250 to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia.

Grant 119 Nicholas Kopeloff, research associate in bacteriology, New York State Psychiatric Institute and Hospital \$100, to investigate bacillus acidophilus milk for the prevention and treatment of summer diarrhea in babies.

Grant 143 Cleveland J White MD 104 South Michigan Avenue Chicago \$150 to investigate the local general and prophylactic aspects of superficial fungus diseases of the skin.

Grant 152 C W Greene, professor of physiology and pharmacology, University of Missouri School of Medicine \$300, to investigate the reaction of the coronary system to drugs.

Grant 164 E J Jackson, associate professor of pharmacology, Emory University School of Medicine, \$200 to investigate the antagonism between soluble barbitol and insulin.

Grant 166 Jern Oliver professor of pathology, Howard Laboratories, Johns Island College of Medicine, \$200 to investigate experimental nephritis in the frog.

Grant 168 N I Schreiber, research fellow Department of Pharmacology, Western Reserve University \$250, to investigate the excretion of mercury after oral administration.

Grant 169 C W Greene professor of physiology and pharmacology, University of Missouri School of Medicine \$250 to investigate the pharmacology of camphor and camphor derivatives.

Grant 170 Moyer S Fleisher, professor and director of Department of Bacteriology and Hygiene, St. Louis University School of Medicine \$250 to investigate serum sickness.

Grant 171 Ernest C Dickson professor of Department of Public Health and Preventive Hygiene, Stanford University School of Medicine \$250, to investigate therapeutic procedures against coccidioid granuloma.

Grant 174 Trent B Johnson Sterling professor of chemistry, Yale University \$250, to investigate protein sugar fractions and their antigenic properties.

Grant 180 A H Mafoney, head of the department and professor of pharmacology, Howard University School of Medicine \$200 to investigate picrotoxin barbiturate antagonism.

Grant 182 R R Krecke, chairman of the department and associate professor of pathology, Emory University School of Medicine, \$250 to investigate bone marrow stimulation.

Grant 186 Department of Pharmacology, Western Reserve University, \$370, to investigate the excretion of metris in syphilis therapy.

Grant 189 Moyer S Fleisher professor and director of Department of Bacteriology and Hygiene, St. Louis University School of Medicine \$250 to investigate serum sickness.

Grant 189 O W Barlow, assistant professor of pharmacology, Western Reserve University School of Medicine \$300 to investigate the effects of a series of analeptics against pentobarbital, tribrom ethanol and chloral hydrate.

Grant 191 Robert Gesell, professor of physiology, University of Michigan Physiology Laboratory \$250 to investigate action potentials involved in the control of respiration.

Grant 192 Carl J Wiggers professor of physiology, Western Reserve University School of Medicine, \$250 to investigate the effect of drugs on the coronary circulation in intact dogs.

Grant 193 J P Quigley, senior instructor in physiology, Western Reserve University School of Medicine \$150, to investigate gastro-intestinal motility.

Grant 194 Sara A Riedman, Columbia University College of Physicians and Surgeons \$200, to investigate the effect of a high fat or ketogenic diet on the susceptibility of animals to convulsions of experimental origin.

Report of the Committee on Scientific Research for 1933

During 1933, eighty-four applications for grants have been received. Thirty-seven awards have been made, the amount awarded is \$9,935. Thirty-seven applications have been declined, and ten are under consideration. The new grants support research in various fields of medicine. In all cases the money has been paid to the financial officer of the institution with which the grantee is connected, the grants being disbursed on requisitions by grantees, at the same time accurate accounts being kept of the disbursements. Recent reports by the grantees indicate that their work is making good progress except perhaps in one or two instances. The results of work under thirty-six grants prior to 1933 have been published or are in actual course of publication. The results of work under twenty-seven grants prior to 1933 are in the course of preparation for publication. In the case of twenty-three grants prior to 1933 active work is still in progress but in several cases reports on results have been published. Refunds amounting to \$1,191.78 have been made from grants.

The committee begs leave to recommend that as nearly as possible the same appropriation be made for 1934 as for 1933, namely, \$12,550 for grants in aid of medical research and \$1,200 for the expenses of the committee.

Financial statement for 1933 is presented, also brief accounts of the grants pending at the end of 1932 and a list of the grants made in 1933.

Respectfully submitted

COMMITTEE ON SCIENTIFIC RESEARCH OF
THE AMERICAN MEDICAL ASSOCIATION

N W JONES, Portland, Ore

Term expires, 1934

MARTIN H FISCHER, Cincinnati

Term expires, 1935

LUDWIG HEKTOEN, Chicago, Chairman.

Term expires, 1936

C C BASS, New Orleans

Term expires, 1937

JOHN J MORTON, Rochester, N Y

Term expires, 1938

GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH NEW GRANTS—1933

Grant 273 Gregory Schwartzman Mount Sinai Hospital New York, \$400 for study on antibodies to Rous sarcoma agent by local skin reactivity.

Grant 274 William C Rose University of Illinois Urbana \$300 for study of unknown dietary essential in casein.

Grant 275 John Guttman Post Graduate Medical School and Hospital New York \$400 for study of electric current produced by cochlea on stimulation by sound.

Grant 276 Jessie L King Goucher College Baltimore \$75 for study of effect of cortical extract on suprarenalctomized rats.

Grant 277 Gustav Zechel University of Illinois College of Medicine \$260 for study of growing malignant cells by moving photomicrographs.

Grant 278 Carl C Speidel University of Virginia Medical School \$100 for study of the myelin nerve sheath with polarized light.

Grant 279 E C Faust Tulane University \$800 for continuation of studies on Strongyloides stercoralis.

Grant 280 W T Dawson University of Texas School of Medicine \$200 for work on the relations between the chemical constitution and toxicity of cinchon alkaloids.

Grant 281 Arthur Knudson and Lloyd Ziegler Albany Medical College \$325 for study of the remote effects of rickets in rats.

Grant 282 Maurice B Visscher University of Illinois College of Medicine \$200 for study of the mechanical efficiency of the heart.

Grant 283 Philip B Armstrong, Cornell University Medical College, \$150 for study of drug action in relation to enervation of the heart.

Grant 284 Helen C Coombs New York Homeopathic Medical College and Flower Hospital \$600 for study of the bromide treatment of experimental convulsions.

Grant 285 M G Seelig Barnard Free Skin and Cancer Hospital St. Louis \$200 for a study of the carcinogenic action of dibenzanthracene 1, 2, 5, 6 and of scarlet red.

Grant 286 F H Pike Columbia University \$600 for study of the effects of successive experimental lesions of the nervous system.

Grant 287 Thomas D Masters, Springfield Hospital Springfield \$100 for work on available dextrose in certain common foodstuffs.

Grant 288 James L O Leary Washington University, \$175 for work on the nervous mechanisms controlling blood pressure.

Grant 289 Harry J Deuel Jr University of Southern California \$300 for further study of the sexual variation in carbohydrate metabolism.

Grant 290 Harry Goldblatt Western Reserve University \$150 for study of experimental hypertension in dogs.

Grant 291 C Alexander Hellwig St Francis Hospital Wichita \$50 for work on the thyroid gland and on thyrotropic substance in human urine.

Grant 292 Ludwig A Emge Stanford University School of Medicine \$200 for study of transplantable benign tumors during pregnancy.

Grant 293 Arthur Grollman Johns Hopkins University \$200 for study of the effects of the hormone of the suprarenal cortex.

Grant 294 Robert Hegner Johns Hopkins University \$300 for a study of the relation between intestinal starch and infections with protozoa.

Grant 295 W R Tweedy Loyola University School of Medicine \$350 for chemical studies on parathyroid hormone.

Grant 296 Alexander S Wiener Jewish Hospital of Brooklyn \$100 for work on agglutinogens M and N.

Grant 297 Erma A Smith Iowa State College \$150 for study of effect on the rat of sublethal amounts of illuminating gas.

Grant 298 Lewis H Hitzrot Philadelphia General Hospital \$100 for study of the therapeutic effect of alternate negative and positive pressure.

Grant 299 S W Ranson Northwestern University \$250 for study of cutaneous nerves in man.

Grant 300 J M Wolfe Vanderbilt University \$100 for study of histology of anterior hypophysis.

Grant 301 Allen D Keller University of Alabama \$500 for study of functions of brain stem.

Grant 302 Erwin Brand and G F Cahill New York State Psychiatric Institute and Hospital \$250 for research on cystinuria.

Grant 303 C C Speidel, University of Virginia Medical School \$250 for study of living nerves.

Grant 304 Frederic A Gibbs Boston City Hospital Boston \$200 for work on the convulsive center in the cat brain.

- Grant 305 John R Murlin, University of Rochester \$500 for study of the effect of sex hormones on energy metabolism
- Grant 306 S S Lichtman Mount Sinai Hospital New York \$350 for further study on estimation of bile salts in body fluids
- Grant 307 E K Marshall, Jr., Johns Hopkins University \$200 for study of the action of iodine compounds on experimental exophthalmic goiter in guinea pigs
- Grant 308 John L Ulrich Johns Hopkins University \$250 for study of the reflex system in the cat
- Grant 309 Carroll L Birch University of Illinois School of Medicine \$300 for work on assay of urine for sex hormone of the anterior pituitary

STATE OF WORK UNDER PREVIOUS GRANTS

I COMPLETED DURING THE YEAR

Completed means that the work immediately aided by a grant has been concluded that full account has been made of the expenses and that the results of the work have been published or are in the course of publication

Grant 105 1927 \$1800 to H B Ward University of Illinois for study of life history of broad fish tapeworm endemic in man in northern Minnesota. For history of the grant and previous publication of results of work under it see the report of the committee for 1931. Articles not listed previously. Essex H E Early Development of *Diphyllobothrium Latum* in Northern Minnesota *J Parasitol* 14 106 1927. A New Larval Cestode Probably *Hymenolepis Cuneata* a Tapeworm of a Wild Duck *ibid* 18 291 1932. Dolley J S Preliminary Notes on the Biology of the St Joseph River *Am Midland Naturalist* 14 193 1933

Grant 107 1927 \$500 to H L Huber Chicago for work on the chemical and immunologic properties of the pollens of hay fever and allied conditions. Huber H L Critical Analysis of Information Obtained from Hay Fever Sufferers *J Allergy* 2 45 1930. Huber H L and Harsh G F A Summer Dermatitis Caused by a Common Weed *ibid* 3 578 1932. The following articles are in course of pub-

lication. Studies in Pollen Chemistry 1 An Evaluation of the Scarification Test as a Quantitative Measure of the Allergic Activity of Pollen Extracts 2 Miscellaneous Chemical Studies on the Pollen of the Large Ragweed (*Ambrosia trifida*) 3 The Tryptic and Peptic Digestion of Extracts of the Pollen of the Large Ragweed (*Ambrosia trifida*) 4 On the Question of a Volatile Fraction of Ragweed Pollen and Its Possible Etiologic Significance

Grants 177 and 192 1930 W T Dawson University of Texas School of Medicine Galveston \$250 for chemical and physiologic study of alkaloids of the cinchona series. Dawson W T and Newman S P Acquired Allergic Corneal Reactions to Quinine But Not to Quinidine or Quinine J A M A 97 930 1931. Sanders J P and Dawson W T Efficacy of Quinidine in Malaria J A M A 99 1773 1932. Bevil H G Hydroquinidine in Malaria *Am J Trop Med* 12 473 1932. Dawson W T Sanders J P and Tomlinson L M Differentiation of Optically Isomeric and Related Cinchona Alkaloids by Quinine Sensitive Subjects *J Immunol* 24 173 1933. Hone C T and others Hydrocinchonidine and Hydrocinchonine in Malaria *Am J Trop Med* 13 437 1933. This work is continued under grant 280, 1933

Grant 184 1930 Herbert F Thurston Indiana University Indianapolis \$300 for study of the suturing of blood vessels. Thurston H F and Lamb E B Circular Suture of Blood Vessels An Experimental Study *Arch Surg* 27 786 1933

Grant 187 1930 A R Johnston University of Cincinnati \$1000 for a study of the toxic action of poisonous amines. Fischer M H Suer W J and Johnston A R Colloid Chemical Properties of Some Protein Amine Compounds *Arch Path* (in course of publication)

Grant 195 1930 Helen T Parsons University of Wisconsin \$300 for further study of the physiologic effects of high protein diets (see grant 175, 1930 and 227 1931). Parsons Helen T and Kelly E The Effect of Heating Egg White on Certain Characteristic Pellagra Like Manifestations Produced in Rats by Its Dietary Use *Am J Physiol* 104 150 1933

Grant 196 1930 Ward W Summerville Institute of Pathology Western Reserve University \$150 for a study of the effects of anemia of the kidney. Summerville Ward W Hanzal R F and Goldblatt H Urea Clearance in Normal Dogs *Am J Physiol* 102 1 1932. The work is continued under grant 290 1933 to Harry Goldblatt

Grant 200 1931 C A Dragstedt Northwestern University Medical School \$250 (Van Zwalenburg Fund) for a study of experimental appendicitis and related problems. Dolyns G J and Dragstedt C A Intra Intestinal Pressure and Absorption from the Intestine *Proc Soc Exper Biol & Med* 30 707 1933

Grant 204 1931 Alan M Chesney Johns Hopkins Hospital \$1000 in aid of work on immunity in syphilis. Chesney A M Turner T B and Grauer F M Studies in Experimental Syphilis *Bull Johns Hopkins Hosp* 52 145 1933. A second and final article is in course of publication in the *Bulletin of Johns Hopkins Hospital*

Grant 207 1931 Maurice L Cohn National Jewish Hospital Denver \$250 for work on the cultivation of the tubercle bacillus (refund 11 cents). Corper H J and Cohn Maurice L Routine Clinical Examination for Tubercle Bacilli in Microscopic Negative Sputums by Various Culture Methods *J Lab & Clin Med* 18 515 1933. Cohn M L An Analysis of Loewenstein's Method for Isolating Tubercle Bacilli from Blood *J Infect Dis* 52 214 1933. Corper H J and Cohn M L The Nutrient Quality of Eggs for Growing Tubercle Bacilli *Am J Hyg* 18 1 1933

Grant 211 1931 Ward Giltner and I Forest Huddleson Michigan State College \$1500 for an investigation of Brucella infection in swine and in workers in packing plants (refund \$969 89). Huddleson I T Johnson Howard J and Hamann E E A Study of Brucella Infection in Swine and Employees of Packing Houses *J Am Vet Med A* 83 16 1933

Grant 213 1931 Harold G Grayzel The Jewish Hospital of Brooklyn \$500 for a study of experimental amyloidosis (refund \$27 14). Grayzel H G and others Experimental Studies in Amyloidosis *Proc Soc Exper Biol & Med* 28 172 1930. Final report in course of publication (*Arch Path*)

Grant 216 1931 W R Tweedy, Loyola University School of Medicine Chicago \$750 for continuation of work under grants 143 and 146 1928 on the parathyroid hormone. McJunkin T A Tweedy W R and Breuhaus H C The Parathyroid Hormone *Arch Path* 14 649 1932. Tweedy Wilbur R and Torigoe Masamichi Chemical Studies on a Parathyroid Hormone *J Biol Chem* 99 155 1932

Grant 214 1931 Harry J Deuel Jr University of Southern California School of Medicine \$600 for work on ketosis. Deuel Harry J Jr and Culick Margaret The Sexual Variation in Starvation Ketosis *J Biol Chem* 96 25 1932. Deuel H J Jr Machay Eaton M Jewel Paul W Gulick Margaret and Grunewald Carl F Studies on Ketosis III *J Biol Chem* 101 301 1933

Grant 215 1931 Daniel A McGinty Emory University Georgia \$150 for a study of the absorption of lactic acid dextrose and oxygen by the heart muscle in continuation of work under grant 185 1930. McGinty D A and Miller A T Jr Studies on the Coronary Circulation II The Absorption of Lactic Acid and Glucose and the Gaseous Exchange of Heart Muscle *Am J Physiol* 103 712 1933

Grant 217 1931 F B Hart and C A Elvehjem University of Wisconsin \$600 toward a study of phosphorus in rachitic and normal blood. Stare F J and Elvehjem C A The Phosphorus Partition in the Blood of Rachitic and Nonrachitic Calves *J Biol Chem* 97 511 1932. Elvehjem C A and Kline B E Calcium and Phosphorus Studies in the Chick *J Biol Chem* 103 733 1933

Grant 219 1931 Norbert Enzer Mount Sinai Hospital Milwaukee \$100 for an investigation of the gases produced by the combustion of x-ray films. Ballard Grace An Investigation of the Gaseous Decomposition Products of X-Ray Films *Radiology* 20 18 1933

Grant 222 1931 C E Burget University of Oregon Medical School \$0 toward investigation of absorption from the closed intestinal loop. Schwichtenberg C and Burget G F Closed Loop Fluid *Proc Soc Exper Biol & Med* 20 16 1931. Smith Vera The Isoterial Flora

of Isolated Intestinal Segments, *J Infect Dis* 18 295 1931 Moore, Philip, H., Lloyd, R. W., and Burget G. E. The Development of Strongyloides in the Experimental Host *Am J Hyg* 18 114 1933

Grant 244 1932 Theodore Cornbleet University of Illinois Medical School \$250 for study of self sterilization of the skin Cornbleet Theodore Self Sterilizing Powers of the Skin, *Arch Dermat & Syph* 27 756, 28 526 1933

Grant 245 1932 M. S. Burman Hospital for Joint Diseases New York, \$200 for study of the fluorescence of cartilage (refund \$182.22) Sutro Charles J., and Burman Michael S. Visualization of the Biliary System by Fluorescence *J A M A* 99 2024 1932 Burman, Michael S. and Sutro Charles J. Fluorescence of Cartilage Exposed to Filtered Ultraviolet Radiation *Arch Path* 15 537 1933

Grant 251 1932 Esther B. Tietz University of Cincinnati \$250 for work on so called pseudopregnancy in rabbits (refund \$5.02) Tietz E. B. The Humoral Excitation of the Nesting Instinct in Rabbits, *Science* 78 316 1933

Grant 252 1932 Bernhard Steinberg Toledo Hospital \$250 for work on protection of the peritoneum against infection Steinberg Bernhard A Rapid Method of Protecting the Peritoneum Against Peritonitis *Arch Surg* 24 308 1932 Steinberg Bernhard An Improved Method of Protecting the Peritoneum of Dogs Against Fatal Colon Bacillus Infection, *Proc Soc Exper Biol & Med* 20 1018 1932 Steinberg Bernhard and Goldblatt Harry Protection of Peritoneum against Infection *Surg Gynec & Obst* 57 15 1933

Grant 256, 1932 Allen D. Keller University of Alabama \$500 for work on the functions of the brain stem See grant 301 1933 Keller Allen D. Observations on the Localization in the Brain Stem of Mechanisms Controlling Body Temperature *Am J M Sc* 185 746 1933 D'Amour M. C. and Keller, A. D. Blood Sugar Studies Following Hypophysectomy and Experimental Lesions of Hypothalamus *Proc Soc Exper Biol & Med* 30 1175 1933 Keller A. D. Hare W. K. and D'Amour, M. C. Ulceration in Digestive Tract Following Experimental Lesions in Brain Stem *Proc Soc Exper Biol & Med* 30 772 1933

Grant 257 1932 M. G. Seelig, Barnard Free Skin and Cancer Hospital St. Louis \$500 for work on blood diastase in cancer (refund \$356.70) Tureen Louis L. Blood Diastase in Cancer *Arch Path* 15 834 1933

Grant 262 1932 C. Alexander Hellwig St. Francis Hospital Wichita, \$100 for study of the effect of iodine on the thyroid gland of the white rat Hellwig, C. Alexander Die Lebenskurve der nordamerikanischen Schilddrüse Endokrinologie 12: 323 1933 Hellwig C. Alexander Histologic Changes in the Thyroid Gland of the Rabbit Following Injection of Urine *Arch Path* 15 321, 1933 (The work is continued under grant 291, 1933)

Grant 260, 1932 Frank R. Menne University of Oregon \$150 for study of the structural changes in the heart in hyperthyroidism Menne F. R., Jones N. O., and Jones N. W. Changes in Myocardium of Rabbits etc (in course of publication in *Archives of Pathology*)

Grant 263 1932 H. J. Deuel, Jr. University of Southern California \$500 for a study of the cause of difference in carbohydrate metabolism between the sexes Butts Joseph S. and Deuel Harry J. Jr. The Sexual Variation in Carbohydrate Metabolism *J Biol Chem* 100 415 1933

Grant 264, 1932 William H. Welker University of Illinois Chicago \$200 for the preparation and study of hematin in its relation to the benzidine and other tests for blood Johnson Clarence A. The Peroxidase Activity of Hematin *Arch Path* 16 667, 1933

2 INCOMPLETE

A Work under the grant completed, account rendered of expenses but results not published fully

Grant 118 1927 \$1,000 to Edward Reynolds and E. A. Hooton Harvard University, for study of the mechanism of erect posture

Grant 167 1929 \$500 to Hans Jensen, Johns Hopkins University for aid in the chemical and physiologic study of toad poisons (refund \$60.81) Jensen Hans and Chen K. K. Chemical Studies on Toad Poisons *J Biol Chem* 87 741 and 755, 1930 Jensen Hans *Science* 75 53 1932

Grant 181 1930 Erwin Brand New York State Psychiatric Institute and Hospital \$700 for research in cystinuria (refund \$366.61) See grant 302 1933

Grant 182 1930 Icie G. Macy Merrill Palmer School Detroit \$500 for a study of vitamins A and B in human breast milk Donelson Eva and Macy Icie G. Human Milk Studies *Am J Physiol* 100 470 1932

HERMAN L KRETSCHMER, Treasurer

AUDITOR'S REPORT

January 31, 1934

To the Board of Trustees,

American Medical Association Chicago, Illinois

Dear Sirs

In accordance with instructions, we have examined the accounts of the American Medical Association, for the year ended December 31, 1933, and have prepared therefrom, and append hereto the statements undermentioned

Exhibit "A"—Balance Sheet as at December 31, 1933

Exhibit "B"—Income Account, for the year ended December 31, 1933

Schedules for the year ended December 31, 1933

Schedule "1"—Journal Operating Expenses

Schedule "2"—Association and Miscellaneous Expenses

In our opinion, based on our examination and information furnished to us the accompanying Balance Sheet and relative Income Account set forth the financial condition of the Association as at December 31, 1933 and the result of its operations for the year ended on that date subject to the following qualifications and observations

(1) The inventories of Materials Supplies and Work in Progress in the amount of \$89 398 49 are stated in accordance with affidavits sworn to by responsible officials of the Association and have not been confirmed by us in any way

(2) In accordance with the established practice of the Association no provision has been made for (a) accrued interest on bonds (b) membership dues unpaid (c) accrued salaries and wages (d) accrued property taxes for the year 1933 and (e) accrued legal fees

(3) Subscriptions paid in advance represent an estimated amount based on cash received for subscriptions for the year 1934 received in the month of December 1933 This conforms with the method used in prior years

(4) Advance payments on publications represent an estimated amount of prepaid subscriptions to *HYGIEA* \$104 514 87 plus \$38 095 28 received in advance for January advertising and directory sales and service

During the year ended December 31 1933 the Association wrote down the value of its real estate to the extent of \$40 000 00

to provide for an estimated decrease in the value of its realty holdings. The aforesaid write-down was charged to Capital Account. We were informed that this charge of \$40,000.00 to the Capital Account would be brought to the attention of the Board of Trustees at its next meeting for proper approval.

We have received a letter from Messrs. Loesch, Scofield, Loesch & Burke, acting as attorneys for the Association, stating that during the year ended December 31, 1933, four lawsuits against the Association or against some official for whose alleged libel the Association was sought to be made liable, have been definitely terminated without liability for damages against the Association. Also that at December 31, 1933, there is one remaining lawsuit still pending with respect to which the attorneys are hopeful of a favorable outcome and termination of same during the year 1934. We have also received a certificate from an official of the Association stating that there are no contingent liabilities at December 31, 1933, other than the lawsuit aforementioned which it believes will be decided favorably to the Association.

Fidelity insurance is carried against the undermentioned officers and employees of the Association in the amounts here stated:

Dr. Olin West, General Manager	\$10,000.00
Dr. Herman I. Kretschmer, Treasurer	10,000.00
F. C. Shelly, Cashier	10,000.00
F. A. Hoffman, Assistant Cashier	2,000.00
Sundry Employees (eight \$1,000.00 each)	8,000.00
Total Fidelity Insurance	<u>\$40,000.00</u>

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK, MITCHELL & CO

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association

While no appeals from actions by state associations have been made during the year, the work of the Council has approximated the amounts of previous years. To the Council comes a steady stream of inquiries, complaints and demands concerning ethical subjects. Most of these arise from some economic situation and fall naturally into one of four classifications: (1) to be sure that contemplated action is strictly within ethical principles, (2) to learn how far departure from the established principles can extend without serious results, (3) a justification of a violation of the principles on the ground that others are doing so, and so why not they or (4) complaints against situations, occurrences or individuals with the demand that the national organization apply corrective measures. Actual situations are described by some, requesting opinions as to the ethical or unethical standing of them. Others cite hypothetical situations with the same request.

Careful consideration is given to all letters, and such help and advice are given as seem proper in each case but care always is taken not to commit the Council beyond its constituted limits or good judgment. Considerable time is spent and effort made to find past decisions and reports of the Council and actions by the House of Delegates that might be applicable to the situation at hand. Frequently appreciation and satisfaction are expressed by the correspondent, but many times dissatisfaction, criticism and fault finding that the officers of the Association do not quell the evils complained of.

The larger proportion of the writers have complaints to make demanding correction by the Judicial Council or the officials of the American Medical Association of situations as they appear to the writers. This correspondence comes largely from individuals, but a fair amount is from county medical societies or their committees. Running through all of it there can be felt a sense of inadequacy, of lack of courage or of inability to handle a situation locally either because it is too large in point of numbers or because of the prominence or influence of the individuals or groups complained of. The most frequent complaint and demand for rectification concern the publicity that attaches to a number of well known clinics and individuals. The next most frequent complaint is against alleged unethical practices of groups and clinics. To all these and similar complaints and inquiries the explanation is made that the Judicial Council is neither a legislating body nor a prosecuting board that legislation rests in the House of Delegates elected by the state associations as their representatives that prosecution is the duty of the county medical society that the Judicial Council is a court to interpret the laws and ethics of the medical profession and to adjudicate those matters brought to it from the state associations under the constitution and by-laws.

In bringing these matters to the House of Delegates and the profession at large, the Council expresses no opinion as to the justness or unjustness of the complaints. It conceives it to be its duty to give this House some conception of the trend of mind of the members of the Association and the extent of that trend for such use as the judgment of the House may indicate. It also conceives it to be its duty in this time when it is evident that many of the members are straining at the ethical leashes which curb their desires to point out that there is but one code of ethics for all, be they group clinic or individual and be they great and prominent or small and unknown. It is but a principle of sound ethics that the greater or more prominent an individual or a group may be the more scrupulous should be the observance of the principles of ethics by them. In bringing this matter before the House the Council makes no charge or implication against any particular individual or group. It realizes that the great and prominent are news and that there is no legal means of avoiding the publication of such news. It believes that the majority of the great and prominent avoid publicity so far as it is in their power and adhere to the Principles of Ethics most carefully. However it has knowledge that there are others of whom this is not true. Under the present constitution the situation is the primary responsibility of the county and state associations as it properly should be the Judicial Council having authority only on appeal from deci-

sions of the state associations. The only exception provided is chapter XI, section 12, of the By-Laws, which provides that "The House of Delegates shall have the power to discipline or expel a member of the American Medical Association on recommendation of the Judicial Council." The Judicial Council frequently is called on to initiate procedures against members. It has declined to do so except on the most flagrant, indefensible and unquestionable violations of the Principles of Ethics, feeling that in view of its judicial rather than its accusative functions and its remoteness from the immediate environments complained about it would be unwise to be the body initiating charges. Whether or not there should be some change in authority or procedure is a matter for decision by the House of Delegates.

During the past year, some of the basic beliefs and principles of the medical profession have been attacked and invaded more seriously and extensively than at any time before. An organized and financed campaign for a socialized system of furnishing medical care to a large proportion of the population has apparently crystallized its plans and begun its propaganda with the millions of certain foundations backing the effort. Practice of medicine by government in all the history of medicine in this country never has invaded the field of the private practitioner with his individual families as has the United States government through the Emergency Relief Administration. This is a complete and undisguised example of 'state medicine.' The avidity with which in general the government's offer was received can be explained only on the basis of an acute economic situation in the profession itself. The occurrence must be considered as a temporary expedient only, due to the unparalleled stress of the times, and must be discontinued as rapidly as the stress on the profession is relieved. A number of societies refused to enter into agreements whereby their members would be bound to provide services and accept compensation directly at the hands of the government. In some instances, official committees of state medical associations and county medical societies have strongly recommended to their members that they continue to provide medical service to all in need and refuse to accept compensation from the government for such services. One of the strongest holds of the profession on public approbation and support has been the age old professional ideal of medical service to all, whether able to pay or not. That ideal is basic in our ethics. The abandonment of that ideal and the adoption of a principle of service only when paid for would be the greatest step toward socialized medicine and shortly state medicine which the medical profession could take. All our arguments as to better service to the people, freedom of choice of doctor, individual service, and maintenance of high grade medical service by highly qualified doctors would be as naught if such service were not available to a vast proportion of the people.

There is no question that medical charity is badly abused and that the past two years of public support of vast number of unemployed have added thousands to that number of paupers we have always with us, people who never have worked and never will, who are content to live on public charity. It conceivably may be that this number may have become so great that the burden of their medical care should be borne by the community as are their other necessities of life. Perhaps the time has come when the profession should distinguish between the temporary and the chronic indigent and demand that the community relieve the private practitioner from furnishing free care to the chronically indigent. But the temporarily indigent those who when able paid for medical care according to their ability to pay should still be the charge of the medical profession in their period of distress.

There have been widespread inquiries and complaints concerning the practice of medicine by hospitals, the division of fees between hospitals and doctors, the acceptance of commissions or rebates by ophthalmologists from opticians, the extensive unethical instances of contract practice particularly in the Pacific Coast states. Concerning all these matters it is sufficient to say that the wide extent of an unethical practice does not make it ethical. Ethics has to do with principles not numbers or locality. A procedure unethical in one part of the country cannot be ethical under the same circumstances in another. Because the percentage of rebate is large in com-

parison, and in a year amounts to a considerable sum, and although many of the practitioners in a specialty may accept those rebates, the acceptance is no more ethical than for the general practitioner to accept a rebate on the occasional truss he may prescribe. The Judicial Council deprecates such ignoring of ethical principles, not only because of the extent of the practices but because in many instances the plea of financial necessity cannot be offered as an excuse. The Council can only publicize the abuses and express its severe condemnation of them. It has no power in itself of control or correction.

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association

I MATTERS REFERRED BY THE HOUSE OF DELEGATES

1 In 1931 the House of Delegates requested the Council to make a classification of foreign medical colleges. Since it was found, for diplomatic and financial reasons, impracticable to do this, a study was made of the number of Americans studying in Europe. When it was learned that well over a thousand such students were enrolled in medical faculties abroad, the facts were brought to the attention of licensing bodies and a joint committee was created to deal with this problem. As a result of its negotiations and recommendations, the Federation of State Medical Boards of the United States, and most of the individual state boards, have adopted procedures designed to discourage students who are not acceptable to our own medical schools from migrating to other countries for their medical training with the expectation of returning to the United States to practice.

2 In 1931 the House of Delegates also instructed the Council "to investigate and make recommendations looking to the establishing of proper qualifications of physicians who shall engage in special practice." At the last annual session the Council reported the results of its study and was further authorized to express its approval of such examining boards as conform to the standards which the Council shall formulate. The procedures of existing boards have been analyzed, and the Council is preparing, as rapidly as possible, a statement of essentials to which all special examining boards may be expected to conform.

3 At the New Orleans session the House of Delegates requested an analysis of hospital staffs with a view to determining how many of the physicians connected with hospitals are members of the American Medical Association. The amount of clerical work involved has prevented a check of all the 6,437 hospitals in the country, but a sampling of a large number shows that 87 per cent of the staffs of these hospitals were members of the American Medical Association.

Since the management of hospitals is a function of ownership, it does not seem to be practicable for the Council or for the American Medical Association to lay down a rule that only members of the county society may be given hospital appointments. Obviously, there would be no way of enforcing such a rule. However, it is believed that in all institutions where the staff members have a voice in the selection of their colleagues, an effort should be made to bring into the local society every physician who may be regarded as eligible for a hospital appointment.

4 Two years ago the House of Delegates adopted a resolution urging the Council to aid the smaller hospitals in improving their standards and efficiency. What the Council is doing along this line is reported in paragraph 17.

5 At the last session the House of Delegates called attention to the excessive number of applicants for admission to medical schools. It has been found that this condition exists in other professional fields as well. It is directly related to the enormous

increase in the number of college students since the war. Figures recently available show that the numbers enrolled in institutions of higher learning bear a ratio to the whole population in England of 1 to 1,150, in Scotland, 1 to 455, and in the United States, 1 to 125. The facts are being reported to the college authorities in order that their students may be warned that admission to a college does not automatically guarantee admission to one of the professions.

6 At the Milwaukee session a resolution was adopted requesting the Council to ascertain whether medical students might not receive training in those basic procedures necessary to conduct successfully the business of a medical practice. This question is being investigated by the Association of American Medical Colleges, which has not as yet made its report.

7 Another resolution called on the Council to investigate the size and scope of a teaching clinic and the extent to which medical schools are engaging in the competitive practice of medicine. This problem was made the topic of a symposium at the Annual Congress on Medical Education, Licensure and Hospitals in February and further investigations are being made. The Council is not ready to report at this time.

8 Of the resolution introduced by Dr. Louis J. Hirschman, Michigan, the following items were referred to the Council:

(c) Devising a course of lectures and demonstrations related to medical ethics, economics, office practice and business details, relationship of physician to patient and public and the fundamental purposes and activities of county, state and national organizations and causing their inclusion in curriculums of approved colleges.

This is being treated in connection with the recommendation described in paragraph 6.

(e) A study and devising of a plan that will abolish the so-called state board examinations (often farcical and not at all competent to determine a candidate's qualifications) and in lieu of such examination accept the certification of an approved medical college as to the candidate's training and graduation.

The Council is not convinced that it would be desirable to abolish the state examinations for licensure and substitute therefor a medical diploma. The plan has already been tried in this country and was generally considered a failure. However, since the proposal involves the revision of state laws, and since the American Medical Association does not intervene in purely state affairs, it would seem that this matter might be referred to the constituent state societies for such action as they deem appropriate.

9 Another resolution of the House of Delegates requested the Council to undertake a study of schools of occupational therapy. Such a study is being carried out and it is hoped that a report will be available at the Cleveland session.

10 The Council has actively cooperated with the Committee on Mental Health in accordance with the provisions adopted by the House of Delegates.

II PUBLICATIONS

11 The Council has prepared material for five special numbers of THE JOURNAL and published the Proceedings of the Annual Congress on Medical Education, Licensure and Hospitals.

12 Revised lists of hospitals approved for internships and residencies have been made available and are in great demand.

13 The usual data concerning medical schools and hospitals are being prepared for the forthcoming edition of the American Medical Directory.

III MEDICAL EDUCATION

14 During the last ten or fifteen years, advances have been made in many phases of medical education. New problems also have arisen. The time, therefore, seems ripe for a comprehensive resurvey of medical education and, with the generous support of the Board of Trustees, such a study is now being undertaken.

15 At the request of the State Board of Regents, the Council made an inspection of the University of Georgia School of Medicine in April 1933 and submitted certain recommendations. Since no action had been taken looking toward a fulfillment of the Council's requirements, approval of the school was withdrawn at the last meeting of the Council (February 1934).

16 Anticipating that the surplus of premedical students who find themselves unable to gain admission to the recognized

schools in this country may find their way into the universities of the Spanish speaking countries to the South of us an attempt is being made with the assistance of the Secretary of State and the Pan American Union to secure official information regarding the standards of medical training that prevail in Latin America

IV HOSPITALS

17 During the year 1933, 755 hospitals were visited by members of the Council's staff These were distributed as follows

Approved for interns or residencies or applying for such approval	206
Tuberculosis sanatoriums	258
Negro hospitals	47
Other hospitals	244

In addition there were inspected

Schools of occupational therapy	4
Schools of physical therapy	4
Schools of laboratory technique	15

The tuberculosis hospitals for the first time have been included in the Council's routine survey With the cooperation of the national associations in this field, it is expected that more complete and more reliable information about the institutional care of tuberculous patients will be available than ever before

Complying with the request of the House of Delegates (paragraph 4) the Council has included in its inspections more than 200 of the smaller hospitals Without attempting to force all of these institutions into the same mold, the members of our staff have been able to give considerable assistance to some of these small hospitals by suggesting improvements in organization or methods of operation

18 At the invitation of the American Hospital Association, a joint meeting was held with its Council on Public Relations' Division of Medical Practice and certain fields of mutual interest were designated for cooperative study

19 Reports for the year 1933 showing the number of unoccupied hospital beds may be summarized as follows

	1929	1933
Governmental	65 652	68 399
Nongovernmental	114 715	148 376
Total	180 367	216 775
General hospitals	123 025	155 021
Special hospitals	57 342	61 754
Total	180 367	216 775

With a daily average of 155 000 unoccupied beds in general hospitals, it would seem to be unnecessary to invest more money at the present time in institutions of this sort

REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association

Dr John E Lane, for thirteen years a member of the Council on Scientific Assembly and for much of that time its chairman died at his home in New Haven Conn Oct 17 1933 For many years Dr Lane represented his state association in the House of Delegates of the American Medical Association and as a member of that body rendered distinguished service as a member of important committees and commissions A physician true to the highest ideals and traditions of his profession, Dr Lane rendered devoted service in the discharge of every duty imposed on him by his fellows As a member of the Council Dr Lane endeared himself to his associates through his unflinching courtesy through his unswerving loyalty to the

cause of scientific medicine and to the American Medical Association, and through his ready willingness to bear his full share of every responsibility

For several years a program known as the "Clinical Lecture" program has been presented on the first two days of each annual session Many prominent members of the professions of this and other countries have contributed and have made splendid presentations dealing in a thoroughly practical manner with subjects of general interest In some years the attendance has not been as large as the high quality of these lectures merited while in other years large audiences have been attracted The response over the entire period has been of such a nature as to indicate clearly a widespread interest in the program and an apparent desire on the part of many physicians that it be continued This part of the program of the Scientific Assembly will hereafter be designated "General Scientific Meetings" and will be presented on Monday and Tuesday at each annual session At this meeting a group of distinguished practitioners and teachers will offer contributions dealing with various subjects of important interest to the general profession

The regular Annual Conference of Secretaries of the Sections with the Council was held in December and nearly all the sections were represented The secretary who could not attend forwarded a written communication concerning the status of the program in his charge The Council again expresses commendation of the zealous and efficient services of the officers of the sections of the Scientific Assembly

One session of the Section on Miscellaneous Topics will be given over to a program on Forensic Medicine Dr Ludvig Hektoen will serve as chairman and Dr Harrison Martland as secretary

Another session of the Section on Miscellaneous Topics will be devoted to scientific discussions pertaining to Nutrition, under the chairmanship of Dr James S McLester, with Dr William S McCann as secretary

The usual arrangements for section meetings have been made No resolutions or memorials have been submitted to the Council during the year

The American Mind in Medicine—What should attract us all is a study of the growth of the American mind in medicine since the starting of the colonies As in a mirror this story is reflected in the literature of which you are the guardians and collectors—in letters, in manuscripts in pamphlets in books and in journals In the eight generations which have passed, the men who have striven and struggled—men whose lives are best described in the words of St Paul, in journeyings often, in perils of water, in perils in the city, in perils in the wilderness, in perils in the sea in weariness and painfulness in watchings often, in hunger and thirst, and in fastings—these men of some of whom I have told you somewhat have made us what we are With the irrevocable past into which they have gone lies our future since our condition is the resultant of forces which, in these generations have molded the profession of a new and mighty empire From the vantage ground of a young century we can trace in the literature how three great streams of influence—English French and German—have blended into the broad current of American medicine on which we are afloat Adaptiveness lucidity and thoroughness may be said to be the characteristics of these Anglians, Gallic and Teutonic influences, and it is no small part of your duty to see that these influences the combination of which gives to medicine on this continent its distinctly eclectic quality are maintained and extended—Sir William Osler Some Aspects of American Medical Bibliography Address delivered before the Association of Medical Librarians 1902

THE OCCURRENCE OF LEAD IN CEREBROSPINAL FLUID

Lead poisoning is no novelty in medicine, its effects in producing pathologic changes in the body have been known almost as long as it has been employed in industry and the arts. Lead "colic" and lead "palsy" have long been recognized in medical literature. Credit for first correlating the most obvious manifestations of intoxication by lead is usually given to Tanquerel des Planches who studied the subject about a century ago. Although lead has been regarded by many writers as the most important of the industrial hazards that lead to special disease, the incidence of industrial lead poisoning is said to be declining, thanks to the widespread introduction of prophylactic measures. According to Aub,¹ about a hundred and fifty industries involve some exposure to lead. The dusty trades are the most hazardous and include the manufacture of white and red lead, of storage batteries and of pottery, as well as painting, printing and the mixing of rubber.

Two features, of late, have become involved in the problem of plumbism. One is the method of treatment, initiated by Aub and Minot, that depends on the parallel metabolism of lead and calcium.² The severe symptoms can be relieved by administration of large doses of calcium in the form of milk and salts of calcium, whereby a deposition of lead in the bones is effected. After disappearance of the acute symptoms, this regimen is replaced with one containing as little calcium as possible. With this a condition of acidosis is initiated, large doses of phosphoric acid or ammonium chloride being given to produce a negative calcium balance, thus tending to liberate lead slowly from the bones so that it will be excreted.

The other feature is the growing recognition that lead is widely distributed in nature, so that plants grown on soils that contain the element may acquire lead. Thus it finds its way insidiously into the body in

food. The U S Department of Agriculture has found it desirable to attempt to establish a maximum permissible content of lead in edible products. It has been remarked that in view of this almost ubiquitous occurrence of lead one would expect it to be a common constituent of human excreta, owing to the ingestion of food materials containing lead, this is found to be the case. The average amount of lead in the feces of normal individuals with no undue exposure to lead was found to be approximately 0.08 mg per gram of ash.³ Its presence in feces does not, however, imply that it is present also in the body tissues, ingested lead may not be absorbed. According to investigators⁴ at the Montreal General Hospital, ten years' experience in examination of the urine indicates that the presence of lead is the rule and not the exception. The average amount is 0.1 mg per liter. Contamination during collection of samples is excluded. These observations fit in with those recorded by Kehoe and Thamann.⁵ Urine of individuals suffering from lead poisoning, or of those unduly exposed to lead in their work, may contain much larger quantities than 0.1 mg per liter. The differences between health and disease are therefore quantitative and not qualitative.

The development of spectrographic methods has greatly facilitated the investigation of minute traces of lead.⁶ In studies at Montreal,⁴ lead was found in the cerebrospinal fluid of every individual known to be suffering from lead poisoning. Lead was found also in isolated cases not presenting histories of undue exposure to the metal. In these cases, with one exception, the amounts were, however, small compared with those found in lead poisoning. An attempt was made to induce the appearance of lead in the cerebrospinal fluid by means of acidosis. Acidosis was produced by the administration of ammonium chloride, and the degree of acidosis was determined by the carbon dioxide combining power of the plasma. Whether lead was or was not liberated from the body was determined by the amount of lead in the urine during acidosis compared with that found before acidosis. Of twenty individuals suffering from a variety of neurologic conditions other than lead poisoning, and in whom no lead was found in the cerebrospinal fluid before acidosis, lead was found in the cerebrospinal fluid in five cases during acidosis. As before acidosis, however, the amounts found were small. Rabinowitch and his co-workers again emphasize the fact that lead readily attacks the central nervous system. Cerebrospinal fluid has been found to contain as much as 1 mg per liter,⁶ or ten times that found in the urine of normal individuals. Its distribution in the body may be widespread. This

⁶ Aub J. C. Fairhall L. T. Minot A. S. and Reznikoff, Paul. Lead poisoning. Medicine Monographs 7, 1926

accounts for the fact that lead poisoning may simulate almost every other disease of the central nervous system. Whether the minute quantities often present have any bearing whatever on obscure nervous symptoms is an important question for serious consideration in the future.

CHOLESTEROL IN THE ORGANISM

Although cholesterol has long been recognized as a widespread component of the animal organism and a substance that can be identified with considerable ease by a biochemist, the physiologic behavior of this peculiar sterol has been little understood until comparatively recent times. In the earlier days attention was primarily focused on the fact that cholesterol is the most conspicuous and abundant component of gallstones, and likewise that it is a characteristic constituent of nervous tissue. Early, too, was the recognition that cholesterol is a highly complex alcohol and that it appears to occur regularly in some quantity in the tissues and fluids of the body. In such material as the bile, blood, milk, liver, kidney and suprarenal cortex it is present not only in the free state but also in combination with several fatty acids as cholesterol esters. The sebum, or secretion of the sebaceous glands, seems to abound in cholesterol derivatives.

With this information, the little definitely known about the functional rôle of the ubiquitous sterol has been tantalizing. Some progress has been initiated by the introduction of methods for estimating more exactly the content of cholesterol in the blood. As a consequence it is possible to speak today of hypocholesteremia and hypercholesteremia. In nephrosis, diabetes and certain types of atherosclerosis, for example, the body appears to be overloaded with cholesterol even when the diet is not overabundant in this component. In some of the infections, however, cholesterol tends to disappear. Naturally one is led to infer that in such cases it is highly probable that disturbances in synthesis or decomposition as well as in excretion of cholesterol play an important part.

Plants contain sterols of various sorts somewhat related to cholesterol in organic structure and physicochemical behavior. According to Schoenheimer,¹ these are not absorbed by the animal organisms. Consequently, cholesterol must be synthesized by animals, and the evidence for this long delayed conclusion now seems convincing.² There are growing indications, too, that cholesterol can be destroyed by the human organism. According to Dam,³ this is not due to the intestinal bacteria. Recent investigations by Schoenheimer and Breusch⁴ at the University of Freiburg in Germany lead clearly to the assumption that in the tissues

cholesterol is continually being formed and destroyed. Either a positive or negative balance may be found depending on experimental conditions, i. e., synthesis may be in excess of destruction or vice versa. Thus, in experimental animals when moderate amounts of cholesterol were administered, a smaller amount of cholesterol was synthesized. When large amounts of cholesterol were given, a considerable part was destroyed. Large amounts of fat or carotene had no effect on the cholesterol balance. Bile acids increased destruction of cholesterol, probably on account of more ready absorption from the intestine. These observations afford a basis for new concepts in the consideration of what cholesterol may really signify in the body.

HUMAN STERILIZATION IN GERMANY AND THE UNITED STATES

Recent legislation in Germany attempting to decrease the incidence of the allegedly hereditarily unfit by sterilization on a large scale has aroused world-wide interest. Several of the Berlin letters in *THE JOURNAL*¹ have dealt with this program. The core of the law enacted July 14, 1933, which went into effect Jan. 1, 1934, has been translated as follows by Peter:²

Those hereditarily sick may be made unfruitful (sterilized) through surgical intervention when, following the experience of medical science, it may be expected with great probability that their offspring may suffer severe physical or mental inherited damages.

The hereditary sick, in the sense of this law, is a person who suffers from one of the following diseases: inborn feeble-mindedness, schizophrenia, circumscribed insanity, hereditary epilepsy, hereditary Huntington's chorea, hereditary blindness, hereditary deafness, severe hereditary physical deformity. Further, those may be made unfruitful who suffer from severe alcoholism.

It has been estimated that approximately 400,000 must soon undergo sterilization.² The larger portion of these are suffering from inborn feeble-mindedness.

Application for sterilization may be made by the individual and will be received from a national licentiate physician attesting that the applicant has been instructed concerning the nature and consequences of the operation. For those legally incapable of managing their own affairs, guardians, courts, legal representatives or trustees may make application. Several safeguards are provided to prevent miscarriage of justice. Seventeen hundred special courts and twenty-seven hereditary health supreme courts are newly and especially constituted for reviewing the cases. All applications must be in writing. Jurisdiction for the decision rests in the court in the district in which the applicant resides. No judge can serve as presiding officer in one of these special courts in a case in which he has rendered decision appointing guardianship. The proceedings of these courts are not public. The courts are obligated to institute all necessary investigations,

² Peter W. W. *Cerriman's Sterilization Program* *Am J Pub Health* 24: 187 (March) 1934

and physicians are required to testify completely without regard to professional secrecy. The verdict of the court must be signed by all who participated in the decision including the reasons for it. If the decision is for sterilization it remains inoperative for one month, during which time appeal may be filed. Finally, the authorized operation must be performed only in a hospital and by a national medical licensee.

Sterilization of the unfit is not a new idea in the United States. As many as twenty-seven states have legislation for human sterilization in effect, though there have been thirty which adopted such legislation at one time or another.³ Indiana on March 9, 1907, was the first state to adopt a compulsory eugenic human sterilization act. This law was, however, declared unconstitutional in 1921 and a new one was not adopted until 1926. In the interval, numerous other states have enacted legislation providing for human sterilization under certain circumstances. Most of these laws have been tested in the courts, the most important being the *Buck v. Bell* decision, rendered by the federal Supreme Court in 1927. The right of society to "prevent those who are manifestly unfit from continuing their kind" was affirmed in this decision. Another important case, tried in the Utah supreme court in 1929, was concerned not with the constitutionality of human sterilization laws but with the necessity for reasonable proof of the hereditary nature of the condition for which sterilization was ordered. The case of *Davis, Warden, v. Walton* was decided on the basis that insufficient evidence of the inheritance and inheritability of the condition had been produced, and mandatory sterilization was therefore not allowed.

On the basis of state legislation in force, about twelve thousand individuals had been sterilized up to 1932.³ It has been reasonably established that the operations of vasectomy or salpingectomy applied have had no deleterious physical or psychologic effects on those so treated. What the effect will be on the primary purpose of decreasing inherited mental defects is as yet impossible to determine, because the number is too small and the duration too brief. Certainly every conceivable effort should be made to follow the course of those sterilized and the progeny of their blood relatives.

Apparently widely different schemes for human sterilization are being applied in Germany and the United States. In Germany, mass sterilization is presumably being carried out. A more gradual evolution of the practice and principles has occurred in this country. Judging from the uncertain biologic foundation on which human sterilization rests, the latter would seem a less dangerous procedure. While recognizing the possible potential value of sterilization, the medical profession can perhaps serve its purpose best by retaining a scientific detachment in assessing the biologic and social results of the programs now in force.

Current Comment

DEHYDRATION IN INFANCY

Dehydration of infants is receiving far more serious consideration at present than it received earlier in the century. Not only is its seriousness for the patient more clearly recognized, but the attendant clinical conditions have gradually become far better understood. When persistent diarrhea or vomiting is encountered for any of a diversity of reasons, it is no longer merely the loss of water that challenges attention. The fluids of the body are saline solutions in which certain inorganic ions are nicely balanced. Loss of water is usually attended with loss of these mineral components of the organism, with a resultant disastrous upset in the equilibrium of the inorganic elements. The basic elements tend to leave the body in considerable measure in the stools. As recently pointed out anew,¹ if acid ions were excreted in the urine in a normal proportion, the body would suffer merely from deprivation of water and salt, the total fluid remaining in the body having a normal salt concentration. However, in severe dehydration the volume of urine is scanty, so that the acid ions are not adequately excreted. This retention of acid ions is undoubtedly one of the principal causative factors in the development of acidosis. Mere administration of saline solutions fails to remedy many of these situations, hence a device for promoting diuresis has been recommended. According to pediatricians¹ at Cornell, the primary aim of the initial treatment should be the restoration of an adequate flow of urine. They find that hypertonic solutions of dextrose administered intravenously serve this purpose. When combined with hypodermoclyses of saline solution they fulfil the three desiderata of immediate treatment by furnishing fluid and electrolytes and stimulating renal function. Improvement in clinical condition and acid-base status of the blood has resulted from this treatment. Obviously the use of hypertonic dextrose solutions is advisable only during the earlier stages of dehydration when oliguria or anuria is present. Once an adequate flow of urine is established and can be maintained by administration of fluids, the use of a diuretic solution would only defeat the purpose of further attempts to replenish body water.² Dehydration is fairly common in children, especially as a complication of other abnormal conditions. Under most conditions all that is required is attention to and encouragement of drinking more water. Difficulties arise when persistent vomiting or other alimentary disturbance requires the use of some other route of administration. Then rectal introduction, parenteral injection and other artificial methods must be used as temporary expedients. At the same time losses of fluid, particularly as sweat, must be minimized as much as possible. In no cases are these corrections of the water balance anything but palliative. Truly pathologic disturbances require treatment of the underlying alimentary, renal, hyperthermic or other disorder.

RESURVEY OF MEDICAL EDUCATION

The Council on Medical Education and Hospitals, with the cooperation of the Association of American Medical Colleges and the Federation of State Medical Boards of the United States, is planning a comprehensive resurvey of medical education. Dr Herman G Weiskotten, dean of the Syracuse University College of Medicine, will make the field studies. In addition to the inspection of schools, the Council will undertake a reexamination of the methods and objectives of medical education.

MEDICAL BROADCASTS

ALABAMA

State Medical Election—Dr William M Cunningham, Jasper, was chosen president of the Medical Association of the State of Alabama at its annual meeting in Birmingham April 19. Dr Douglas L Cannon, Montgomery, was reelected secretary for five years. Montgomery was designated as the place for the 1935 meeting, April 16 18.

ARKANSAS

State Medical Election—Dr Melvin E McCaskill Little Rock, was chosen president-elect of the Arkansas Medical Society at its annual convention in Little Rock April 16-18. Dr Fergus O Mahony, El Dorado, was installed as president. Other officers elected are Drs Albert M Elton, Newport, Silas C Fulmer, Little Rock, and Flem D Smith, Blytheville vice presidents, and William R Brooksher Jr Fort Smith and Royal J Calcote, Little Rock secretary and treasurer respectively. The next annual meeting will be held in Fort Smith.

CALIFORNIA

Hospital News—The new acute unit building of the Los Angeles County Hospital was dedicated April 15. Operation of the unit began in December 1933 when the obstetric division on the eighth floor was put into service.

Osman with Another Alias—E K Osman or Osmun whose activities as a fraudulent insurance representative were described in THE JOURNAL March 11 1933 page 745 was recently arrested in San Andreas for similar operations. Using the names Dr Crawford and Mulliberg he would call on physicians as a representative of various insurance companies,

stating that he had been delegated to select a medical examiner in each town. He would usually collect about \$3 50 from each physician interviewed, which, he claimed, was the fee charged for blanks and containers to be purchased by the selected examiners. He has been returned to Ventura, where he was also wanted by the authorities, it is reported.

Tuberculosis Control—The Santa Barbara County Health Department instituted its third annual campaign against tuberculosis among school children, April 9. In the last three years, 4,363 children in the county, outside the city of Santa Barbara, have had the tuberculin test, or more than 82 per cent of the school population. Of this number, negative results were obtained in 3,606. Of the 757 children who gave positive reactions, all have had roentgenograms made and most of them have had complete examinations, 123 are yet to be seen by the specialist, the state health department reported, April 7, and 692 reactors were found without present evidence of illness or progressing disease. Fifty-six were found to be definitely ill.

COLORADO

Dinner to Dr Levy—Dr Robert Levy, Denver, was entertained at dinner at the Cosmopolitan Hotel, April 4, by the Medical Society of the City and County of Denver, in recognition of his completion of fifty years in the practice of medicine. An oil portrait of Dr Levy was presented to the medical society by Dr John W Ames, on behalf of friends, and accepted by Dr Frank W Kenney. It will be placed in the society's library. Dr Levy has served for many years as professor and head of the department of otolaryngology of the University of Colorado School of Medicine, and organizations of which he has been president include the American Laryngological, Rhinological and Otolological Association, 1915, Colorado State Medical Society, and Denver County Medical Society. He is one of the founders and has been three times president of the Denver Clinical and Pathological Society.

DISTRICT OF COLUMBIA

Medical Bills in Congress—Bills Introduced S 3479, introduced by Senator King, Utah and H R 9362 introduced (by request) by Representative Norton New Jersey, propose to amend the act regulating the practice of the healing art in the District of Columbia (1) by substituting the corporation counsel of the District of Columbia for the United States district attorney as a member of the commission on licensure to practice the healing art and (2) by transferring to the corporation counsel for the District of Columbia, from the United States district attorney, the duty of instituting legal proceedings for the enforcement of the act.

District Scientific Assembly—The annual two day scientific assembly of the Medical Society of the District of Columbia opened, May 2, in Washington at the Mayflower Hotel. A public meeting Wednesday evening was addressed by Dr George Burgess Magrath, professor of legal medicine, Harvard University Medical School, Boston. Speakers on the program included the following physicians:

Harry Stack Sullivan, New York, Psychiatric Aspects of Medical Patients
Matthew White Perry Clinical Manifestations of Nondysenteric Amebiasis
Thomas A Groover Blazing New Trails for Organized Medicine
David Davis Bronchoscopy in Suppurative and Malignant Disease of the Lung
William P Herbst Jr Traumatic Rupture of Kidney
John Minor Practical Aspects of Diabetes
Samuel Desoff Gonorrheal Endocarditis of the Pulmonary Valve
Thomas W Mattingly Recurrent Thrombosis of the Portal Vein with Splenectomy
Francis Clark Grant Philadelphia Major Trigeminal Neuralgia

FLORIDA

Hookworm Campaign—A campaign against hookworm has been launched by the Florida State Board of Health. Emergency relief funds have been requested to carry on the work, which is concerned chiefly with sanitation of schools. A recent survey showed the disease to be prevalent to an alarming degree it was stated. During the month of March alone, out of 11,606 specimens examined 4,946 proved positive for hookworm, giving a percentage of 42.6.

Society News—A symposium on cancer of the breast was presented before the Dade County Medical Society in Miami April 6 by Drs Walter C Jones Jr Iva C Youmans and Frazier J Pavton. Dr Joseph H Luciman presented a case of angina pectoris treated by x-rays. At a recent meeting of the DeSoto-Hardee Highlands County Medical Society in Avon Park Dr Leland F Carlton Tampa discussed the

economic problem of arthritis—The program of the Duval County Medical Society, April 3, was devoted to a symposium on arthritis by Drs. Julian E. Gammon, Frank L. Fort and Wilfred M. Shaw, Jacksonville.—The Orange County Medical Society was recently addressed in Orlando by Dr. Paul D. White, Boston, on heart disease.

ILLINOIS

State Medical Meeting at Springfield, May 15-17—The eighty-fourth annual meeting of the Illinois State Medical Society will be held at Springfield, May 15-17, under the presidency of Dr. Philip H. Kreuscher, Chicago. The secretaries' conference will be Tuesday morning. The oration in medicine will be delivered, Tuesday afternoon, by Dr. Walter L. Biering, Des Moines, Iowa, President-Elect, American Medical Association. His subject will be "Diagnosis of Heart Disease: Historical Development of Its Recognition." Dr. Frederic J. Cotton, Boston, will present the oration in surgery Wednesday morning on "Ten Years of Progress in the Treatment of Fractures." Dr. Kreuscher's presidential address in the afternoon will be on "The Doctor and His Community." Tuesday afternoon will be devoted to a symposium on pneumoconiosis, with Drs. Frank J. Jirka, Royd R. Sayers, Washington, D. C., and Jerome R. Herd, Richard H. Jaffe, and Clarence O. Sappington all of Chicago participating. The following physicians, among others, will present papers:

Woodruff L. Crawford, Rockford, Survey of Allergic Diseases in Childhood
Thomas D. Masters, Springfield, Benign Melituria
Richard P. Herndon, Springfield, The Value of Symptoms
Frederic W. Bureky, Evanston, Agranulocytosis
Walter M. Whitaker and Walter D. Stevenson, Quincy, Membranous Nephritic Infections of the Lower Respiratory Tract in Children
William A. Evans, Chicago, Heart Disease: Past, Present and Future
Austin A. Hayden, Chicago, Fractures of the Nose
Michael Zeller, Chicago, Management of Allergic Vasomotor Rhinitis
Francis L. Lederer and Louis Zolo, Fishman, Chicago, Rationalization in Therapy of Laryngeal Tuberculosis
Joseph C. Beck, Chicago, Rehabilitation of the Voice After Laryngectomy
Ira H. Lockwood, Kansas City, Mo., The Aid of the X Rays in the Diagnosis of Breast Tumors
Benjamin H. Orndoff, Chicago, Radiotherapy and Electrosurgery in the Treatment of Cancer of the Breast

Fracture demonstrations will be conducted intermittently through the general sessions. The veterans' dinner, Tuesday evening at the Leland Hotel, will be addressed by Dr. Thomas B. Williamson, Mount Vernon, on "Why the Medical Commission?" Edward Hayes, national commander, American Legion, "The Legion Program as It Affects Organized Medicine," and Dr. Edward H. Cary, Dallas, Texas, Past President, American Medical Association on "The American Medical Association—Its Duty to Its Members and the Nation's Veterans of the World War." The meeting of the woman's auxiliary of the state society will be held at the Knights of Columbus Building, May 15-16.

Chicago

Personal—Dr. Walter W. Hamburger has been appointed clinical professor of medicine in the Division of Biological Sciences, University of Chicago.—Dr. Carl Beck was honored with a reception, March 25, in observance of his seventieth birthday.

Willard Gibbs Medal Presented to Dr. Urey—The presentation of the Willard Gibbs Medal to Harold Clayton Urey, Ph.D., associate professor of chemistry at Columbia University, New York, since 1929 took place at the Stevens Hotel, April 27. William Draper Harkins, Ph.D., of the University of Chicago made the presentation. Dr. Urey spoke on "The Significance of the Hydrogen Isotopes." "Some Differences in the Thermodynamic Properties of the Hydrogen Isotopes" was the title of Dr. Urey's paper before a meeting in the Kent Chemical Laboratory, April 28 under the auspices of the University of Chicago and the Chicago Section of the American Chemical Society. Dr. Urey was awarded the Gibbs medal for his discovery of double weight hydrogen.

INDIANA

Surgeon Sues Township—A physician recently filed suit in the DeKalb circuit court against Franklin township for \$321 on an account for professional services. Action was instituted when the township refused to pay the bill. According to the complaint as reported in the newspapers, a resident of the township was engaged in threshing grain last year when he slipped and fell so that his foot and leg were caught in the threshing machine and crushed. It was stated that the man was without property or credit to procure the necessary aid

and treatment. Since it was believed that the township trustee could not be reached in time to authorize the treatment the man was rushed to the hospital, where it was found necessary to amputate the leg at once. The wound became infected and a second operation was performed to amputate it above the knee. The physician declares that it was necessary to act at once to save the man's life and that there was no opportunity to consult the township trustee, but that the township has refused to pay the bill.

KANSAS

Graduate Clinics—The fourth annual graduate clinics of the school of medicine and the extension division of the University of Kansas, Lawrence, were conducted in Kansas City, April 2-4, by members of the faculty. The following program was presented:

Treatment of Appendix Abscess (Local Peritonitis) Dr. Thomas G. Orr
Dyspnea Dr. Peter T. Bohan
Dropsy Dr. Logan Clendinning
Bronchiectasis Dr. Roy F. Mills
Nonsurgical Treatment of Brain Concussion Dr. Edward T. Gibson
Prolonged Labor Dr. Buford G. Hamilton
Management of Pelvic Infection Dr. Robert D. Irland
Obesity Dr. Edward H. Hashinger
Treatment of Scoliosis Dr. Clarence B. Francisco
Ulcerative Colitis Dr. Ellis Wilhelm
Pneumonia in Children Dr. John Aull and Hugh L. Dwyer
Management of Children Exposed to Scarlet Fever Dr. Frank C. Neff
Collapse Therapy in Tuberculosis Dr. Lawrence E. Wood
Toxic Myocarditis Dr. Joseph E. Welker
Care of Early and Late Burns Dr. Earl C. Padgett
Menorrhagia Dr. Leroy A. Calkins
Infections of the Hand Dr. Laurence P. Engel
Nonspecific Prostatitis, Dr. Nels F. Ockerblad

In addition, Richard L. Scammon, Ph.D., dean of medical sciences, University of Minnesota, delivered the Porter lectures (THE JOURNAL, March 31, p. 1092).

KENTUCKY

Physician Sentenced—Dr. Lawrence M. Spitzelberger, formerly of Bellevue, was recently sentenced to three years in the United States Penitentiary at Atlanta, for violation of the Harrison Narcotic Act.

University News—Leslie B. Arey, Ph.D., professor of anatomy, Northwestern University Medical School, Chicago, delivered the first Phi Beta Phi lecture at the University of Louisville Medical School, March 10, on "Mechanism of Vision in the Retina."

Personal—Dr. William H. Fuller, Mayfield, was recently appointed a member of the state board of health to succeed Dr. Frank L. Johnson, Livermore.—Dr. James O. Nall, Freedom, has been appointed health officer of Caldwell County, with headquarters at Princeton, to succeed Dr. Aubrey Y. Covington.

Society News—Dr. Beatty, Earl Caywood addressed the Garrard County Medical Society, Lancaster, February 15, on diabetes mellitus. This society was recently reorganized after several years of inactivity.—Dr. Stuart P. Hemphill, Danville, addressed the Boyle County Medical Society, February 20 on the value of roentgen rays in diagnosis.—Physicians of Logan County recently organized a county medical society with Dr. Shepard S. McReynolds Jr., Russellville, as president, and Dr. Walter Byrne, Russellville, as secretary.

LOUISIANA

Dr. Menville Awarded Prize—Dr. Leon J. Menville, assistant professor of medicine and roentgenology, Tulane University of Louisiana School of Medicine, New Orleans, was presented with the annual award of the Louisiana Academy of Sciences at its annual meeting, March 17, for his paper on "The Possible Application of a Visualized Lymphatic System to the Cancer Problem." The prize is a medal designed specially for the academy.

Society News—The Orleans Parish Medical Society devoted its meeting March 26, to a symposium on appendicitis, with the following speakers: Drs. Andrew V. Friedrichs, Urban Maes, Frederick F. Boyce, Charles Walter Mattingly and Edward William Alton Ochser. A symposium on diets constituted the society's meeting, April 23, with Drs. Isaac I. Lemann, Manuel Gardberg, Joseph S. D'Antoni and Sydney Jacobs as the speakers.—Dr. Albert M. Abramson, Marks, presented a paper before the Avoyelles Parish Medical Society, Cottonport, March 14 on "Superficial Infections and Wounds."—Dr. George R. Herrmann, Galveston, Texas, was among the speakers before the Fourth District Medical Society at Shreveport, March 6 on "Peripheral Vascular Diseases."

MAINE

Society News—Speakers before the Kennebec County Medical Association, Augusta, March 15, included Drs Leon D Herring, Winthrop, on "Lead Poisoning," and Carl H Stevens, Belfast, "Management of Some Abdominal Emergencies"—At a meeting of the York County Medical Society in Biddeford, April 4, Drs Elton R Blaisdell and Thomas A Foster, Portland, discussed diabetes and children's diseases respectively—A recent meeting of the Portland Medical Club was addressed by Dr John R Hamel on diabetes mellitus

MARYLAND

Dr Woods Named Acting Director of Wilmer Institute—Dr Alan C Woods has been appointed acting director of the Wilmer Ophthalmological Institute at Johns Hopkins University School of Medicine, Baltimore, succeeding Dr William H Wilmer, who will retire July 1. Dr Woods will also become professor of ophthalmology to fill the vacancy caused by Dr Wilmer's retirement. Dr Woods has been associated with the institute since its establishment in 1925, becoming associate professor in 1927. After his return from France in 1919, Dr Woods was made instructor in ophthalmology at the medical school, and, in 1924, associate. He graduated from Johns Hopkins University in 1910 and from Johns Hopkins University School of Medicine in 1914. Dr Wilmer's retirement is in accord with the rule of the university that professors leave the faculty when they are 70 years of age (THE JOURNAL, January 6, p 51)

MASSACHUSETTS

Physician Imprisoned—Dr Percy W Carr, Boston, was committed to the Massachusetts State Prison, February 20, it is reported, for from two and one-half to four years, for attempting to procure an abortion

Dr Lanza Gives Cutter Lecture—Dr Anthony J Lanza, assistant medical director, Metropolitan Life Insurance Company, New York, delivered the Cutter Lecture on Preventive Medicine at Harvard Medical School Boston, April 20. His subject was "Silicosis and Asbestosis"

Personal—Dr John Herbert Waite, Boston, has been made clinical professor of ophthalmology at Harvard University Medical School—Dr Ralph C Wiggan has been appointed surgeon-in-chief of the Massachusetts Memorial Hospitals, Boston, succeeding Dr Charles T Howard, who is resigning after thirty-six years service. Dr Howard will continue as consultant—Dr Charles L Clay, Newton, was recently named medical director of Long Island Hospital, Boston.

Changes at Boston University—Dr Winfred Overholser, assistant commissioner of mental diseases in Massachusetts since 1930 and president of the Massachusetts Psychiatric Society, has been appointed professor of psychiatry at Boston University School of Medicine. He has been on the faculty since 1925. Dr Louis G Howard was named professor of orthopedic and fracture surgery, and Dr Rudolph Jacoby Jr professor of dermatology and syphilology. Dr Frederick W Colburn, professor of otology since 1929, was made professor emeritus, he had been connected with the faculty since 1901. He also received his degree of doctor of medicine at the school. Dr Otto J Hermann was named associate professor of orthopedic and fracture surgery.

MICHIGAN

Society News—Dr William W Bauer Chicago addressed the Henry Ford Hospital Medical Society, Detroit April 10, on "Popular Beliefs That Are Not So"—Dr William P Wherry, Omaha addressed the annual meeting of the Detroit Otolaryngological Society April 25 on "Clinical Application of the Newer Research in Chronic Sinusitis"—At a meeting of the Oakland County Public Health Association in Pontiac March 7, Dr David R Clark discussed "The Psychopathic"—Dr Bruce C Lockwood, Detroit spoke before the society April 4 on "Amebic Dysentery"—A symposium on colitis constituted the meeting of the medical section of the Wayne County Medical Society, April 9, on this occasion Harry M Nimmo, LL.D, editor of the Detroit Saturday Night was presented with honorary membership. A symposium on disturbances of menstruation was presented before the society, April 16 by Drs Lewis E Daniels, Harold Henderson and Milton A Darling all of Detroit.—The Gratiot-Isabella Clare County Medical Society heard Dr Myron G Becker Edmore discuss myelogenous leukemia at its meeting in Alma March 2

MISSOURI

Tuberculosis Surveys—Under the auspices of the Missouri Tuberculosis Association, tuberculosis surveys have been organized in Pettis, Livingston, Atchison, Randolph, St. Charles, Vernon, Nodaway and Saline counties. In some counties the survey will be followed by the tuberculin test and roentgen ray examination of contact children. In Laclede and Lawrence counties, tuberculin tests and roentgen examinations have been given in childhood tuberculosis clinics. Surveys are also being planned in other counties, the medical societies in all of which are cooperating with the tuberculosis associations.

Health at St. Louis—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of about 37 million, for the week ended April 21, indicate that the highest mortality rate (189) appeared for St. Louis and, for the group of cities as a whole, 122. The mortality rate for St. Louis for the corresponding period last year was 118 and, for the group of cities, 11. The annual rate for eighty-six cities for the sixteen weeks of 1934 was 126 as against a rate of 121 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

St. Louis Clinics—The graduate course and clinic conference will be held in St. Louis, May 21-26, under the auspices of the St. Louis Clinics. The programs are to be entirely clinical, covering the various branches of medicine, surgery and surgical specialties. Evening addresses will be presented by the following physicians:

Joseph F Bredeck Public Health Aspects of Tuberculosis
George D Kettlekamp Complications in Pulmonary Tuberculosis
Julius A Rossen What Constitutes Active Pulmonary Tuberculosis in Children?
Louis C Boismiere Useful Drugs in Controlling Symptoms in Pulmonary Tuberculosis
Harry S Crossen Cancer of the Uterus
Quintan U Newell Recent Advances in the Management of Sterility in the Female
Edward Lee Dorsett Diagnosis of Ectopic Pregnancy

Registration for the course may be made with the office of the St. Louis Clinics, 3839 Lindell Boulevard, St. Louis, the fee is \$10.

NEW HAMPSHIRE

State Medical Meeting at Manchester—The one hundred and forty-third annual meeting of the New Hampshire Medical Society will be held in Manchester, May 15-16, under the presidency of Dr Robert J Graves, Concord. Guest speakers will be:

Dr Dean Lewis Baltimore President American Medical Association
subject not announced
Dr William P Murphy Boston Pernicious Anemia
Dr Walter C Alvarez, Rochester Minn What Is Wrong with the Patient Who Feels Tired Weak and Toxic?
Dr Frank E Adair New York Diagnosis and Treatment of Breast Cancer

New Hampshire physicians listed on the program include:
Dr Joseph A Friberg Manchester, Friedman's Modification of the Aschheim Zondek Test for Pregnancy
Dr Donald E Higgins Epping Prolapse of the Uterus During Pregnancy
Dr Bernard P Haubrich Claremont A Case of Phenobarbital Poisoning
Dr Herbert L Taylor Portsmouth Bone Tumors

A symposium on tuberculosis will be presented by S A Petroff, Saranac Lake, N Y and Drs Richard H Overholt, Boston, Adelbert S Merrill Manchester, and Robert M Deming Glencliff. The fifty-year membership gold medal will be presented to Drs Leonard Jarvis, Claremont, and George E Leete Concord. The annual banquet will be given Wednesday evening May 16. Dr James J Powers, Manchester, is chairman for the banquet.

NEW JERSEY

Society News—Dr Alfred Stengel, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City April 13, on "Problems in Medical Diagnosis"—Drs Francis I Borzell and Lyn W Deichler Philadelphia addressed the Essex County Medical Society Newark April 12, on medical economics—Dr Thomas M McMillan Philadelphia addressed the Gloucester County Medical Society Pitman, March 15 on rheumatic heart disease—Dr Russell L Cecil, New York addressed a joint meeting of the Passaic County Medical and Dental Societies Paterson March 8 on Dental Infection and Its Relationship to Systemic Disease.

NEW YORK

Drive Against Diphtheria—A state-wide drive for immunization against diphtheria was recently announced by the state health department. For the first time in five years the number of cases and deaths from diphtheria failed to decline in 1933 and several small outbreaks occurred during the year, according to the state health officer. There are thirteen cities with populations of 10,000 or more in which 35 per cent of the children under 5 years of age have been immunized, but in the remaining fifty-four cities of comparable size the percentages of immunization are much lower. Parents are to be urged in a house-to-house canvass to have their children immunized and various means of publicity will be used. Toxoid distributed by the state health department is the immunizing agent recommended for general use.

State Medical Meeting at Utica—The one hundred and twenty-eighth annual session of the Medical Society of the State of New York will be held in Utica, May 14-16, with headquarters at the Hotel Utica, under the presidency of Dr. Frederick H. Flaherty, Syracuse. General sessions will be held Tuesday and Wednesday afternoons, at which symposiums will be presented on "Hormones Which Influence Growth and Reproduction" by Philip E. Smith, Ph.D., New York; Drs. George W. Corner, Rochester; Robert T. Frank, New York; and Lewellys F. Barker, Baltimore, and on "Forensic Medicine" by Alexander O. Gettler, Ph.D., New York; and Drs. Charles Norris, New York; Harrison S. Martland, Newark, N. J.; and Vernon C. Brusham, Albany. The section on public health, hygiene and sanitation will present a symposium on asphyxia, given by Drs. Pradel J. Flagg, Alvan L. Baruch, New York, and Chevalier Jackson, Philadelphia. Among guest speakers who will address other sections are:

Drs. Hermann L. Blumgart and David D. Herlin, Boston. Treatment of Angina Pectoris and Congestive Heart Failure by Complete Ablation of the Thyroid Gland.

Dr. Ralph M. Lyson, Philadelphia. The Problem of the Premature Infant.

Dr. Joseph V. Knuder, Philadelphia, Jonathan Hutchinson.

Dr. John S. Coulter, Chicago. Work of the Council on Physical Therapy of the American Medical Association.

Dr. Dean Lewis, Baltimore, President, American Medical Association will give an address at the annual banquet at the Hotel Utica, Tuesday evening.

New York City

Hospital News—An examination for an appointment as resident at the Institute of Ophthalmology, Columbia-Presbyterian Medical Center, will be held at the institute, 635 West One Hundred and Sixty-Fifth Street, Friday, May 11, at 3 o'clock.

Changes at New York University—The council of New York University has recently announced the following appointments and changes in title at University and Bellevue Hospital Medical College:

Dr. John Winston Fowlkes, professor of otolaryngology.

Dr. Douglas Symmers, professor of pathology and director of pathologic laboratories.

Dr. Frank W. Co. Tut, associate professor of experimental surgery.

Julius A. Klosterman, Ph.D., associate professor of bacteriology.

Dr. Maurice Brodie, assistant professor of bacteriology.

Dr. Irving Graef, assistant professor of pathology and assistant director of pathologic laboratories.

Dr. Milton B. Rosenbluth, clinical professor of medicine.

Dr. Robert P. Wallace, assistant clinical professor of medicine.

Dr. Lillian C. Warnshius, assistant clinical professor of medicine.

Gibbs Prize to Be Awarded—The New York Academy of Medicine announces that a sum of about \$800 is available under the Edward M. Gibbs Memorial Prize toward original research in diseases of the kidney in 1934. Candidates for the award must be physicians who have been graduated at least three years and residents of the United States. They must submit evidence of research already performed and facilities to prosecute research on the causation, pathology and new methods of treatment of diseases of the kidney. The award may be continued through not more than three years to any one individual. Applications with the required evidence should be sent to the academy, 2 East One Hundred and Third Street, New York, before June 1.

Society News—Lester R. Cahn, D.D.S., addressed the Bronx County Medical Society, April 18, on "Correlation Between Medicine and Dentistry," and Dr. Theodor Blum, also a dentist, discussed importance of medicodental cooperation.

—Drs. Henry B. Richardson and Henry G. Bugbee discussed the medical and urologic phases, respectively, of perinephritis and perinephritic abscess at a combined meeting of the sections on medicine and genito-urinary surgery of the New York Academy of Medicine, April 18. —Dr. Charles L. Janssen

addressed the New York Surgical Society, April 23, on "Melanoma of Rectum." —Drs. George F. Pfahler, Philadelphia, and George B. Lusterman, Rochester, Minn., addressed the Society for the Advancement of Gastro-Enterology, May 3, on "Roentgenologic Diagnosis of Meckel's Diverticulum" and "Etiology, Pathways and Mechanism of Pain and Treatment of Peptic Ulcer," respectively. —Speakers before the Medical Society of the County of New York, April 23, were Drs. Louis E. Phancuf, Boston, on "Diagnosis and Treatment of Placenta Praevia," Harvey B. Matthews, Brooklyn, "Diagnosis and Management of Breach Presentations," and Edward A. Schumann, Philadelphia, "Diagnosis and Management of Persistent Occipitoposterior."

OHIO

Personal—Dr. Walter A. Jaquith, Chicago, has been appointed medical director of the Columbus Mutual Life Insurance Company, Columbus, succeeding Dr. Willis B. Carpenter. —Dr. Dorsey W. Fellers, Bloomville, has been appointed health officer of Seneca County.

Obstetric Society Organized—Representatives of the hospitals in Ohio having twenty-four or more bassinets organized the Hospital Obstetricians' Society of Ohio at a meeting at St. Luke's Hospital, Cleveland, February 24. The purpose of the society is to study maternal mortality and morbidity of the hospitals to establish minimal standards for hospitals in Ohio and to benefit the practice of obstetrics. Dr. Arthur J. Skel was elected president and Dr. Scott C. Runnels, secretary.

Postgraduate Day—The seventh annual "postgraduate day" of the Mahoning County Medical Society, Youngstown, was held April 28, with physicians from the faculty of McGill University, Montreal, as guest speakers. Dr. Jonathan C. Meakins spoke on "Rheumatic Fever Considered as a Specific Infectious Disease" and "Chronic Nontuberculous Pulmonary Disease"; Dr. James B. Collip on "Recent Advances in Anterior Pituitary Physiology"; Dr. John R. Fraser, "The Inflammatory Pelvis and 'Hemorrhage in the Last Trimester of Pregnancy,'" and Dr. Wilder G. Penfield, "Management of Head Injury Early and Late" and "Epilepsy: Classification and Management."

Cincinnati's Health in 1933—The general death rate in Cincinnati during 1933 was 14, as compared with 14.7 for 1932. The infant mortality rate was 55.4, a slight increase from the rate for 1932. Sixty-three deaths were charged to gastro-enteritis in children under 2 years old, an increase from the previous year, when 52 deaths occurred. Forty-seven mothers died from puerperal causes in 1933, as compared with 45 in 1932. Tuberculosis declined from 89.8 to 89.3 per hundred thousand of population. There were no deaths from typhoid among Cincinnati residents, but four imported cases were reported. Heart disease was the principal cause of death. 1,399 persons having died from this cause, 70 more than in 1932.

OKLAHOMA

State Medical Meeting at Tulsa, May 21-24—The forty-second annual session of the Oklahoma State Medical Association will be held at Tulsa, May 21-24. Guest speakers will be Drs. Donald C. Balfour, Rochester, Minn., and Charles F. Craig, New Orleans, who will speak at two general sessions Tuesday and Wednesday mornings. Dr. Balfour's subjects will be "Benign and Malignant Lesions of the Stomach and Their Management" and "The Duodenum" and Dr. Craig's addresses will be on amebic dysentery. Section meetings will be held in the afternoons, and an evening general meeting Tuesday, at which the incoming president, Dr. LeRoy Long, Oklahoma City, will give his official address. The president's reception and dance will be given at the Hotel Mayo Tuesday evening and the annual golf tournament Monday at the Tulsa Country Club. The Oklahoma Pediatric Society will hold a meeting Monday, with Dr. Williams McKim Marriott, St. Louis, as guest speaker.

OREGON

Personal—Dr. Leo S. Lucas, Portland, was elected president of the alumni association of the University of Oregon Medical School at the annual session in Portland, March 14.

PENNSYLVANIA

Physician's Right to Examine Motorist—Judge Norman T. Boose of Somerset County recently ruled, in a trial at Media of a man for alleged drunken driving, that a physician has no right to examine a man for intoxication unless the driver gives his consent. When such an examination is made without the driver's consent, the testimony of the physician is not admissible as evidence the judge asserted. In spite of the ruling, the jury returned a verdict of guilty in the case.

Society News—Drs Grover C Weil and John Henry, Pittsburgh, addressed the Westmoreland County Medical Society, Greensburg, March 8, on "Diagnosis and Treatment of Fractured Pelvis"—Dr Charles Howard Marcy, Pittsburgh, addressed the Lycoming County Medical Society, Williamsport, April 13, on pulmonary tuberculosis—Dr John P Griffith, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, April 5, on "Postoperative Complications and Treatment"—Dr Jacques P GueQuerre, Philadelphia, addressed the Dauphin County Medical Society, Harrisburg, April 3, on dermatology and its relation to the general practitioner—Dr Harry E Mock, Chicago, gave an address on skull fractures and intracranial injuries before the Harrisburg Academy of Medicine, April 17—The tenth councilor district of the Medical Society of Pennsylvania combined its annual meeting with the annual clinic sessions of the Westmoreland County Medical Society, Greensburg, May 3. Among guest speakers were Drs Dean Lewis, President, American Medical Association, and John T King Jr, both of Baltimore, Donald Guthrie, Sayre, president, Medical Society of the State of Pennsylvania, on intestinal obstruction, and William H Guy, Pittsburgh, management of syphilis—Dr Norman H Russell, Timmins, Ont, addressed the Pittsburgh Academy of Medicine, April 24, on silicosis

Philadelphia

Special Meeting on Medical Research—Work of the Philadelphia Institute for Medical Research was presented at a special meeting of the Philadelphia County Medical Society, April 30. Dr Judson Daland, president of the institute, discussed its plans and organization, and other speakers described the research done in the past year on thymus extract. Dr Leonard G Rowntree, director, spoke on "The Accruing Effects of Thymus Extract (Hanson) on Growth and Development in Successive Generations of Rats", Dr Adolph M Hanson, Faribault, Minn, on "Preparation and Nature of an Active Thymus Extract", Jefferson H Clark, on "Histologic Findings in Rats Treated with Thymus Extract (Hanson)", John Lansbury, "Blood Picture in Rats Treated with Thymus Extract (Hanson)", and Henry H Donaldson, Ph D "Applications of the Results Obtained on the Rat to Man." A demonstration of thymus-treated rats was also arranged

Demonstration of Cardiac Diagnostic Methods—Demonstrations of methods of diagnosing and treating heart disease will be held under the auspices of the Philadelphia Heart Association, May 15-18. Sessions will be held at the University of Pennsylvania, Jefferson Medical College, Temple University School of Medicine, Pennsylvania Hospital, Philadelphia General Hospital and the Children's Heart Hospital. Among those who will conduct the demonstrations are

- Dr Edward B Krumhaar General Pathology of the Heart.
- Dr Francis Q Thorp Report of Results of Intravenous Streptococcus Vaccine in Children with Rheumatic Cardiovascular Disease
- Dr Eugene P Pendergrass Roentgen Examination in the Study of the Heart and Great Vessels
- Dr Thomas McCrae Syphilis of the Heart
- Dr Edward L Bauer Heart Lesions Occurring in Children
- Dr Leonard G Rowntree Present Status of Our Knowledge of Hypertension
- Dr William D Stroud Treatment of Acute Arrhythmias
- Dr Joseph B Wolfe Etiology and Treatment of Angina Pectoris

SOUTH DAKOTA

State Medical Meeting at Mitchell—The fifty-third annual session of the South Dakota State Medical Association will be held at the Widmann Hotel, Mitchell May 14-16 under the presidency of Dr Edward W Jones, Mitchell. Mornings will be devoted to medical and surgical clinics given by visiting physicians. Speakers listed on the program include

- Dr Francis E Senear Chicago Modern Treatment of Syphilis
- Dr Fred M Smith Iowa City Peptic Ulcer
- Dr Albert M Snell Rochester, Minn, Unusual Clinical Pictures Associated with Common Duct Stone
- Dr Irving S Cutter Chicago Studies on Capillaries
- Dr Ralph G Willy Chicago Radiologic Findings of Primary Carcinoma of the Lungs
- Dr Frederick A Willus, Rochester Minn Treatment of Congestive Heart Failure
- Dr Stuart W Harrington Rochester Surgical Treatment of Carcinoma of the Breast
- Dr Edgar J Huenekens Minneapolis Care of Infant in First Year of Life
- Dr Joseph C Ohlmacher Vermilion Etiologic and Pathologic Aspects of Some of the More Important Cardiovascular Diseases
- Dr Hiram Winnett Orr Lincoln Neb Osteomyelitis—Treatment Without Frequent Dressings

The annual banquet will be held Tuesday evening May 15 with Dr Irving S Cutter as speaker on State Medicine Its Significance.

TEXAS

Warning Against Rabies—Three dogs suffering from rabies were caught in Dallas within an hour and a half, March 16 newspapers reported. Dr James W Bass, city health officer, issued warning to residents to beware of dogs and to seek treatment immediately if they had been bitten. Rabies vaccine was administered to thirty-seven persons that day. A campaign to force all citizens to muzzle dogs, to have them vaccinated and to buy city licenses was instituted.

State Medical Meeting at San Antonio—The sixty-eighth annual session of the State Medical Association of Texas will be held in San Antonio, May 14-17, under the presidency of Dr Alonzo A Ross, Lockhart. Guest speakers who will address general meetings will be

- C T Freeman Sherman attorney for the association, Actionable Negligence in the Use of X Rays
- Dr James P Simonds Chicago Amebiasis
- Dr Russell M Wilder Rochester Minn, Recent Advances in Endocrinology
- Dr James C Masson Rochester, Malignancy of the Uterus
- Dr Leander A Rely Oklahoma City Diabetic Problems
- Dr Miguel A Bustamante, Mexico City The Virus of Typhus
- Dr Ellis Fischel, St. Louis Surgical Use of Radium

In addition, the guests will speak at special section luncheons and the regular section meetings. Dr Albert H Andrews, Chicago, will be the guest of the eye, ear, nose and throat section. Dr Ross will give his official address at the first general session and Dr Samuel E Thompson, Kerrville, president-elect, will speak on "Present-Day Drift Toward Overprotection and Its Evil Consequences." One general session will be devoted to memorial services. The Texas Neurological Society, Texas Radiological Society, Texas Dermatological Society, the Texas Railway Surgeons Association and a conference of county and city health officers will meet Monday, May 14. The association dinner will be held at the Gunter Hotel, Tuesday evening, followed by the president's reception and ball. Various Texas physicians will give public health lectures in San Antonio churches, Sunday, May 13.

WISCONSIN

Society News—The Ninth Councilor District Medical Society met in Wisconsin Rapids, January 11, with the following speakers: Drs William S Middleton, Madison, on silicosis, Leland C Pomerville, Wisconsin Rapids, perinephritic abscess, and Paul F Doege, Marshfield, work of the cancer committee of the state medical society. Speakers at a meeting of the Portage County Medical Society Stevens Point, March 6, were Drs Joseph Gale, on surgical treatment of pulmonary tuberculosis, William S Middleton, treatment of lobar pneumonia, and Mr J George Crownhart, economic problems facing the medical profession. All were from Madison—Drs Frank N Wilson, Ann Arbor, Mich, and James C Sargent, Milwaukee, addressed the Medical Society of Milwaukee County, March 9, on "Coronary Disease" and "Resection of the Prostate: An Evaluation," respectively—Drs Francis D Murphy and Edmund H Mensing addressed the Milwaukee Academy of Medicine, March 20, on "Complications of Diabetes Mellitus" and "Reducing the Hazards of Intestinal Obstruction" respectively—Drs Elmer W Hagens Chicago, and John E Mulsow addressed the Milwaukee Oto Ophthalmic Society, February 27, on "Anatomy and Pathology of the Petrous Bone" and "Local Lesions of the Mouth in Granulocytopenia" respectively—Dr Samuel Plahner, Milwaukee, addressed a joint meeting of the medical and dental societies of Jefferson County at Watertown, March 28, on causes and prevention of neuroses.

GENERAL

Research Fellowships Established—E R Squibb and Sons have announced plans for establishing fellowships in various institutions throughout the country in connection with the biologic laboratory at New Brunswick, N J. Fellowships with a value of \$1,800 the first year and not more than \$2,200 in subsequent years will be awarded in medicine, biology, chemistry and physics. Applicants must hold the degree of doctor of medicine or doctor of philosophy or an equivalent.

Care of Lepers—The United States Public Health Service in a recent letter to health officers urged that state and local officers arrange to send all lepers found in the continental limits of the United States to the National Leprosarium at Carville La. This institution which has been operated by the service since 1921, is a modern hospital in which every effort is made to provide the best medical and nursing care. At present there are 354 lepers under treatment there. Since 1921 166 persons have been discharged as no longer dangerous.

The service is prepared to defray the expenses of lepers from any state to Carville and will send qualified experts on request to consult with local physicians or to verify the diagnosis

Changes in Status of Licensure—The California State Board of Medical Examiners reports the following

Dr I Jesse Citron Hemet, license restored February 26 placed on probation for five years without narcotic possession or privileges

Dr Ernest N Freeman Glendale, license restored, February 26, placed on probation for five years

The Oklahoma state board of medical examiners has reported the following actions taken at a meeting, March 13

License of Dr John Milton Thompson, Walters, Okla., suspended for five years

License of Dr William Flournoy Griffin Watonga Okla., suspended for one year following his conviction on a charge of violating the Harrison Narcotic Act

License of Dr Richard E. Thacker Oklahoma City, revoked permanently following his sentence to life imprisonment for murder by an illegal operation

Medical Bills in Congress—*Changes in Status* S 822 has passed the Senate, authorizing the Postmaster General to permit the transmission in the mails of poisonous drugs and medicines to cosmetologists and barbers S 1842 has been reported to the Senate, with recommendation that it pass The bill proposes to authorize the dissemination of information relating to the prevention of conception, and articles, instruments, substances, drugs and medicines designed, adapted or intended for the prevention of conception, (1) by any physician legally licensed to practice medicine or by his direction or prescription, (2) by any medical college legally chartered under the laws of any state or the District of Columbia, (3) by any druggist in filling any prescription of a licensed physician and (4) by any hospital or clinic licensed in any state or the District of Columbia S 2455 has passed the Senate, providing that for the purpose of promotion there shall be credited to the officers of the Medical Corps all active service as officers of the Medical Reserve Corps rendered by them between April 23, 1908, and April 6, 1917, with the proviso that no back pay or allowances shall be held to have accrued prior to the passage of the act S 2794 has passed the Senate, amending the longshoremen's and harbor workers' compensation act Among other things the bill would authorize a deputy commissioner to suspend payment of compensation if the injured employee unreasonably refuses to submit to medical and surgical treatment S 3393 has passed the Senate, providing that Osage Indians who are habitual drunkards or habitual users of narcotics may be committed to institutions *Bills Introduced* H R 9230, introduced by Representative Carter, California, proposes to amend the veterans' provisions of the Independent Offices Appropriation Act, 1934, to give the benefits thereof to veterans who enlisted in the United States forces after August 12, 1898, and who served in Cuba

Society News—The American Association of Medical Milk Commissions will hold its annual meeting in Cleveland, June 11-12—The National Society for the Prevention of Blindness announces that four colleges will offer courses for training teachers and supervisors of sight-saving classes during the coming summer, as follows State Teachers College, Buffalo, University of Chicago, University of Cincinnati, and Teachers College, Columbia University, New York Information may be obtained from the society, 450 Seventh Avenue, New York, or from the universities—The Medical Women's National Association will hold its annual meeting in Cleveland June 10-12, with headquarters at the Hotel Cleveland, and under the presidency of Dr Mary O'Malley, Washington, D C—Dr Roy Glenwood Spurling, Louisville, was elected president of the Harvey Cushing Society at its third annual meeting in St Louis, April 5-6, and Dr Louise C Eisenhardt, Boston, secretary The next annual session will be held in New Haven, Conn Active members of the society are engaged in investigative work in neurology, neurosurgery and allied subjects The recent meeting opened with an operative clinic at Barnes Hospital followed by a roentgenologic demonstration, and the afternoon of the first day and the entire second day were devoted to addresses Dr John F Fulton Jr, New Haven, retiring president of the society, spoke on "Relation of the Physiology of the Nervous System to Neurology"—The American Physiotherapy Association, an organization of physical therapy technicians, will hold its annual meeting in Cleveland, June 13-16 Speakers will include Drs Russell L Haden and Wallace S Duncan, Cleveland on 'Arthritis as a General Medical Problem' and 'Low Back Disability Its Etiology and Treatment,' respectively—The American Association of Industrial Physicians and Surgeons will meet in Cleveland, June 11-12, with headquarters at the Hotel Statler

The Danger of Drugs Used for Weight Reduction

The death of a dancer from an overdose of nitrophenol, taken to reduce her weight, was reported in a previous letter The case has led the government to take action to prevent the public from being able to obtain such drugs so easily A letter from the home secretary was read before the Pharmaceutical Society asking if the council of the society would initiate restrictions pending the coming into force of the new pharmacy and poisons act During the discussion it was pointed out that the pharmacist from whom the tablets had been purchased told the girl that she would be well advised to take them only under a physician's orders As far back as September 1933 the manufacturers of the tablets containing the nitrophenol suggested to the home office that the drug should be placed on the poisons list, but nothing was done The first and second fatalities from nitrophenol were recorded in THE JOURNAL, Oct 21, 1933, page 1333, and Feb 17, 1934, page 523 The case that is the subject of this note is the third fatality on record, but serious symptoms have been observed in other cases Nitrophenol reduces obesity by increasing the metabolic rate and evidently is a dangerous remedy for this purpose and should be used with the greatest care

Attacking Locusts from the Air

As reported in a previous letter, a new method of destroying locusts has been devised Mr H H King, formerly chief entomologist to the Sudan government, has left London for northern Rhodesia for the purpose of making experimental attacks on flying swarms of locusts He will discharge clouds of sodium arsenite ahead of the locusts, passing to and fro across their line of advance These swarms may be of great extent They have been observed at sea 1,200 miles from land, and one that crossed the Red Sea in 1889 was estimated to be 20,000 square miles in extent In 1932 Mr King discovered by laboratory tests at Khartoum that the adult locust fell a ready prey to a spray of finely ground sodium arsenite His suggestion to discharge arsenite dust from an airplane on flying swarms of locusts was taken up by the locust control committee of the economic advisory council The damage caused by locusts in tropical and subtropical Africa has been estimated at \$7,500,000 annually Since 1929 the locust control committee has been collecting material for a comprehensive survey of the breeding grounds and migratory habits of the several species of locust With this knowledge and his own expert training, Mr King is in an ideal position to deal with the pest Including the hire of the airplane, the experiment will cost \$21,000 The airplane has been specially fitted with an apparatus for the discharge of the poison dust, which costs \$250 a ton Three tons has been sent to Rhodesia from the only company in Great Britain that could produce the dust of sufficient fineness The discharging apparatus has been fitted to the wings of the airplane, and the airman will be protected from the dust cloud, which will trail behind him as he flies Heretofore there has been no completely satisfactory method of destroying locusts The usual method is to kill them in the immature (hopper) stage by poison baits laid on the ground, but the migratory locust does not eat the bait so readily as the desert hoppers Calculations made by the chemical research department of the war office indicate that the rate at which sodium arsenite powder of the required density will fall raises no difficulty in creating a suitable cloud There is no danger to man or live stock, as natural dissipation quickly

reduces the density to a nonpoisonous level. Compared with poison gas, dust has the advantage of not requiring to be stored in heavy cylinders and in being cheaper.

The Feeding of Children

Much discussion is taking place as to the minimum dietetic requirements of persons subsisting on unemployment pay and as to the amount of money that should be allowed for this purpose. The children of the unemployed furnish a special problem. In the house of commons, a children's minimum committee has been formed to urge that every child shall receive sufficient nourishment for health. It sent a deputation to the prime minister, which made the following proposals: 1 That a daily ration of clean fresh milk should be available for all children attending state-aided schools, for younger children through the public health department, and for expectant and nursing mothers. 2 That it should be made compulsory on local authorities to provide school meals for children who by reason of poverty of their parents or for other reasons are inadequately fed. 3 That the allowance for children of unemployed persons should be substantially increased. 4 That encouragement should be given to the extension on municipal housing estates of schemes of rent rebates, when the family income is insufficient for minimum needs. The prime minister said that he welcomed the formation of the committee and looked forward to cooperation with it.

In a joint letter to the *Times*, the three medical peers—Lords Dawson, Horder and Moynihan—ask that the milk supplied to children be rendered safe for consumption. They state that the supply of milk to growing children will receive strong support from the medical profession, but until purity at the source and during subsequent distribution can be guaranteed all milk should by pasteurization be rendered safe from the risk of causing disease.

Heart Disease and the Workman's Compensation Act

The extraordinarily wide manner in which the workman's compensation act is now interpreted in the courts is shown in a paper on heart disease in workmen read before the Medical-Legal Society by Mr. D. H. Kitchin. He pointed out that, when a workman suffering from heart disease died at work, the courts nearly always treated the death as an accident arising out of his employment (the words of the statute). He considered that this was unjust to the employer and might be prejudicial to a workman in seeking employment. The act laid down that the employer had to pay compensation for personal injury by accident arising out of and in the course of the employment. In the earlier cases the courts held that, if nothing fortuitous or unexpected happened, any mishap could not be attributed to an accident. Thus when a workman ruptured the vessels of his stomach in straining at a fly-wheel of a gas engine this was held not to be an accident. But later decisions reversed this decision, and Lord McNaghten said in the supreme court that such a view would unfairly penalize a workman who put forth his best efforts. In what is now the leading case on the subject, a workman ruptured an aneurysm when performing some light operation—an occurrence that might have happened in his sleep. This was decided in the court of appeal by a majority of three to two to be an accident arising out of his employment. In another case a dipper in a galvanizing shop died of angina pectoris during an interval of the work, and this was held to be an accident arising out of his employment.

The Dangers of Colonic Irrigation and of Enemas

In a letter to the *British Medical Journal* Mr. A. Wilfrid Adams, a Bristol surgeon, reports a case in which a woman suspected to be suffering from acute intestinal obstruction was admitted to a hospital. The house surgeon ordered a turpentine

enema. When Mr. Adams operated a few hours later, the odor and character of the free fluid present in the peritoneal cavity showed that the enema had found its way there, obviously through a perforated gangrenous diverticulum of the sigmoid colon. The enema hastened the woman's end. In another fatal case of diverticulitis it seemed that the same pitiable sequence ensued. Mr. Adams points out that patients who have undergone colonic resection not rarely receive rashly administered enemas within a few hours or days of the operation. These have led to fatal leakage. He also refers to two fatal cases of appendectomy, recorded by Pett, in which leakage at the appendix stump was suspected to have been due to enemas, and virulent peritonitis followed. Another danger was described by Rayner, a Manchester surgeon, in 1932—injury to the mucous membrane of the anus and rectum in the administering of enemas. Rayner saw three such cases in six years. The injury is always grave, for it causes sloughing of the anal canal and rectum, and temporary colostomy is necessary to promote healing. The essential factor in producing the injury is the use of a hard conical nozzle, usually of bone, sometimes of glass, of which the tip is forced through the anal mucosa.

Fatal Dermatitis Due to Dyed Fur

Many cases of severe dermatitis due to the wearing of fur dyed with paraphenylenediamine have been recorded, but the following appears to be the only one that has proved fatal. An inquest was held at Liverpool on a widow, aged 59. Dr. Robert Mackenna, a dermatologist, stated that he treated her for dermatitis of the lower part of the face and the whole of the neck, chest and arms, caused by wearing a fur collar that was dyed. Later she was admitted to a hospital but, although the dermatitis improved, her general condition became worse and she died from heart failure and edema of the lungs. Fur dermatitis had never previously been known to end fatally, but he thought that the heart was in some way affected. Dr. Dilling, professor of pharmacology at Liverpool University, stated that he examined the fur. Two dyes had been used, paraphenylenediamine and para-aminophenol, both of which would cause dermatitis.

Fiscal Measures Obnoxious to Physicians

Great indignation has been aroused in the medical profession of France by reason of the fiscal regulations recently introduced. The law passed last year obliged physicians to keep an account of all the sums they receive, with the name of the clients who paid them. All physicians protested that this constituted a violation of the right of privileged communication. The minister of finance proposed therefore substituting figures for the names of the patients, the latter being recorded in another book which would be kept secret. The physician was, however, compelled to deliver to his client a receipt for the sum each receipt to bear the recorded number of the patient. In this way traps might be set for physicians for certain clients are entitled to deduct from their income the money needed for their treatment in the event of a protracted disease, and in such cases they must present to the controllers of the treasury department the receipts for the sums that they have paid to their physician. If this particular physician was suspected by the controller of having made an inadequate declaration he might be requested to exhibit his books in which would be checked the numbers corresponding to the receipts. This solution of the matter was severely criticized. The Academy of Medicine passed a unanimous resolution condemning the system. During the discussion on the budget the physicians who are members of the chamber of deputies (and

there are a number of them) succeeded in suppressing the obligation of furnishing numbered receipts. But the senate reestablished it on the intervention of Mr. Cuillaux. The budget was returned to the chamber of deputies, which upheld the suppression, and then passed again to the senate, which finally yielded. Physicians are therefore no longer compelled to furnish their clients receipts for all the sums that the latter pay, but they must still keep book account of the sums received, and their books are always open for the inspection of the controllers of the income tax if their attention is called to any apparent discrepancy between the amount of income declared and the visible expenditures of the physician: amount of rent paid, number of domestics, number and type of automobiles, country home, and other items.

Typhoid in Marseilles

The Marseilles Medical Society selected as the topic for its recent annual meeting "Typhoid in Marseilles," where the mortality from the disease is 157 per hundred thousand, as compared with 48 in Paris, 05 in London and 08 in Berlin. Dr. Violle stated that the probable reasons were absence of sewers in several sections of the city and the suburbs, frequency of the pollution of spring water and of wells and, particularly, constant contamination of the shore line (in a sea that has no tide) by sewage. Mr. Teyssourette has made a study of the shell-fish consumed in Marseilles and has made a comparison of the relative number of typhoid bacilli found in the several varieties. Oysters proved to be only a secondary source of infection. It appears that at present it is chiefly the mussels and more rarely the sergheims that are mostly responsible. It is difficult to secure healthy shell-fish at Marseilles, and so long as the sewers empty on the shore typhoid will be prevalent. The only thing that will help is the establishment of rigorous regulations and strict surveillance, which the carelessness and skepticism of the people make exceedingly difficult. Mr. Olmer has noted that the infections observed at present in Marseilles are nearly always due to the Eberth bacillus (98 per cent of the cases, with 1.40 per cent paratyphoid B and 0.22 per cent paratyphoid A). The importance of vaccination is proved by the greater frequency of the disease in women (eighty-nine cases in women as compared with thirty-six cases in men, in a hospital department) and by the less grave type of the disease occurring in vaccinated persons. Vaccination is compulsory in men during their military service. Shell-fish infection in Marseilles has been found to be at the basis of sixty-five out of a hundred outbreaks. Typhoid due to shell-fish is distinguished by its gravity (21.42 per cent of mortality, as compared with 12.37 per cent in the same period for infections not having that origin). Certain peculiarities distinguish this etiologic type of the disease. The incubation period is sometimes shortened. Evolution occurs in two stages after a stage of ordinary gastro-intestinal infection or after an icterus. Diarrhea, hemorrhage and perforation are frequent. Cases occur in which accidents are precipitated as if the typhoid infection were rushing headlong. Blood disorders manifested by modifications of coagulation and of the appearance of the blood clot, are frequent. To explain the rapid course that shell-fish infection often presents, one may imagine a massive inoculation of bacilli through a concentration of microorganisms in the shell-fish, or, rather, of a combined infection, *Bacillus coli*, putrid bacteria and anaerobes exerting their action possibly in situ in the intestine and thus aggravating the effects of typhoid infection. C. Mattei and L. Isenmann reported their experience with serotherapeutic treatment of typhoid, which gave, in general, good results. The Rodet serum was found to be most active in these grave cases. The bacteriophage administered by mouth gave irregular results. Subcutaneous injections proved to be more effective but pro-

duced marked immediate reactions. Autohemotherapy acts favorably on the slow types—likewise simple transfusion of normal blood. Immunotransfusion of the blood of a subject previously vaccinated against typhoid gave excellent results and possibly may become the method of the future. The delirium of typhoid patients is quickly relieved by injections of liver extract in large doses.

The Federal Merger for Research on Nutrition

Federal health administration has been taken over by the Reichszentrale für Gesundheitsführung, which consists of eleven different federal *arbeitsgemeinschaften*, or mergers. The department of general nutrition is under the direction of Professor Reyher. A firm union of all the organizations combined in this department insures the avoidance of dangers that might threaten the enforcement of the common principles and prevents the special interests of any one group gaining the upper hand. In questions requiring special scientific study the federal bureau of health is ever ready to advise the members of the *reichsarbeitsgemeinschaft*, who are recruited from the different schools representing German research on nutrition. In addition to the testing of the modern principles of German science of nutrition research on the biologic value of food products and the care of the foods themselves is being conducted. Emphasis is placed on the hygienic importance of transportation of food products and their distribution among the population. Methods of preserving foods are studied. Furthermore in collaboration with the federal bureau of health, the uses of skim milk and potatoes, as additions to bread, have been investigated.

The investigation of proposed reforms in nutrition constitutes a special field of research. The reform movement has offered to cooperate with the *reichsarbeitsgemeinschaft*. A standing committee has begun to perform practical work, and it appears likely that the objectionable features of the reform movement, as pointed out by men of science, will soon disappear. This committee, in collaboration with the federal ministry for popular education and enlightenment, will control the publicity service, which is suffering from mismanagement, and if attempts are made to oppose such development, action will be taken to eliminate all opposition.

The second department, under the direction of Professor Schliker, has the task of elaborating and establishing dietetic criteria for patients in the hospital and in the spas and health resorts. It is also the duty of this department to establish criteria for the selection and training of the personnel responsible for the nutrition of patients and convalescents.

A special journal will publish results of the research of the *reichsarbeitsgemeinschaft* and the associated committees that have to do with the nutrition of the German people. A separate department will issue reports from time to time on the general nutrition of the people and will announce special diets to be used solely for patients and convalescents. The creation of a popular journal, whose essentials are now being worked out, has been announced by Professor Reiter (president of the federal bureau of health) for the fulfillment of this task.

Observations on the Hormone Regulation of the Circulation

Professor Rein, of the University of Göttingen, reported recently, before the medical society of Frankfurt on Main, on the results of his research on the intact organism with physiologic quantities of hormones. He measured the blood pressure simultaneously in several unopened vessels and thus obtained some insight as to how the whole organic system behaves

toward epinephrine. He concluded that when the muscle is working the blood vessel is not contractible. Physiologic doses of epinephrine, which do not cause pressure fluctuations in the coronary region, produce dilatation in the heart and during rest, constriction in the periphery. If however larger doses are given (0.05 mg for each 30 Kg of body weight) the epinephrine constriction is counteracted by the depressor effect hence in the region of the coronary arteries constriction results. Therefore, the muscle cannot be throttled by physiologic quantities. Not only in the muscle but also in the splanchnic region the same effect may be observed. The same rule applies to the skin. A pronounced constrictive tendency is observed in the suprarenals. Rein cites in evidence thirty experiments on the entirely intact suprarenal vessel. He observed constriction even though dilatation prevailed in the splanchnic region. It is evident therefore, that no considerable increase of pressure can develop as the suprarenal does not furnish the material itself and that the presence of an unphysiologic epinephrine level results in a suppression of the suprarenals.

If the sinus caroticus is clamped off, these are the results: constrictions in the periphery, increase of pressure, increase of heart activity, and dilatation of the coronary arteries. This action is of a purely neuroreflexive nature. The suprarenals play no part in it. The effusion of epinephrine into the circulation takes place independently of the increase of blood pressure.

The function of the suprarenals as regulators of the circulation can be conceived of, according to these observations, as follows. In the organism certain stimuli cause an effusion of epinephrine into the blood, among other things action of the muscle effects a projection of epinephrine but epinephrine does not produce everywhere the constriction that occurs. Constriction, moreover, occurs only where there is physiologic rest and not where there is activity; that is blood is transported from a quiet to an active area. Epinephrine is important because of its leveling action on the blood pressure but it will not of itself lead to increase of blood pressure. When present in the blood it suppresses its secretion from the suprarenal gland. Epinephrine can thus no longer be regarded as exerting physiologic action on the blood pressure. It is not impossible, however, that an increase of pressure may be observed in pharmacologic experiments, just as therapeutic utilization of epinephrine in a similar sense may continue to be upheld.

CAPE TOWN

(From Our Regular Correspondent)

Feb 8 1934

Professor of Forensic Medicine Appointed

The University of the Witwatersrand has recently appointed a professor in forensic medicine. This post has been made possible by the cooperation of the government which contributes a certain amount toward the salary of the professor who acts at the same time as chief district surgeon (police surgeon) for Johannesburg. Heretofore both universities with medical faculties attached to them have refrained from concentrating on this important subject of medical jurisprudence and the courts have several times complained about the nature and quality of the medical evidence tendered. General practitioners or specialists in departments other than medical jurisprudence have given evidence on points on which even an expert on medical jurisprudence might have been diffident in expressing his opinion. On the other hand one must cordially appreciate the excellent work done by district surgeons who have sometimes 'worked up' a case in a manner that would have done credit to any expert. A case that rises to mind is that of *Rex v Hauptfleisch* a homicide case in which the guilt or innocence of the prisoner turned largely on the nature of the burns on the body of the murdered woman. In this case the

district surgeon, Dr Bam, carefully went into the question of the nature of postmortem and antemortem burns, and his conclusions were afterward confirmed in every particular by a committee of experts appointed by the government. As a result, the prisoner was found guilty and hanged. Usually, however, homicide cases are not so carefully worked up. Now that Johannesburg has appointed a professor in forensic medicine, it is likely that Cape Town will follow suit, and it is understood that a similar arrangement will be made.

The First Education Number

The medical journal publishes this month, for the first time, an education number, following herein the example set by THE JOURNAL and some other medical papers. The number is devoted to a description of the work done at Cape Town and Johannesburg, with a full account of the various departments. It shows how rapid has been the progress of medical education in the unions. Indeed, some people hold that this progress has been far too rapid and that more medical men are being trained than can be readily absorbed. That, however, is not the opinion of either of the two principals of our universities with medical faculties. They show, in articles contributed to the education number, that South Africa can still find employment for the medical men it turns out and that a fair percentage of the newcomers have qualified abroad, where the requirements are not quite so exacting as here. A union medical student takes six years to qualify, and the first two years, devoted to chemistry, physics, zoology, anatomy and physiology, are particularly strenuous. Some rearrangement of the curriculum is probably desirable and is at present a matter of consultation between the faculties and the medical association. The views of the principals of the universities are not shared by many of the members of the association, and more than one voice has been raised in protest against flooding the country with medical men. It is perfectly clear that the native territories are understaffed with medical men. The subject is one for the determination of which data are needed that are at present not available.

First Annual Scientific Meeting

Last month the African branches of the British Medical Association met at Dar-es-Salaam for their first annual scientific meeting. The meeting was attended by delegates from England and elsewhere and the Medical Association of South Africa sent a deputation consisting of two of the best known members of their federal council. In the list of subjects discussed tropical diseases were to the fore.

William Darley Hartley

The profession has sustained a great loss through the death, in his seventy-ninth year, of the veteran Dr William Darley Hartley. He was born at Sheffield and did graduate study at Paris before coming to this country. During the campaign of 1879 he suffered from heat stroke—a disability that saved his life for his regiment left without him and was decimated at Isandula; his deputy medical officer being among those mutilated by the natives. Later on he practiced at East London. In 1898 he started practice as a specialist at Cape Town. He had always been interested in medical politics. He established the 'South African League,' a political organization that was at one time very strong. After the Boer War he founded the *South African Medical Record* in 1903 and soon devoted all his time and energy to it. He served on the Colonial Medical Council. He carried on his paper until 1926 when he agreed to sell it to the newly established Medical Association of South Africa which incorporated it with the *Transvaal Medical Journal* and appointed him its first editor. He was elected a life honorary vice president of the Cape Western Branch; he was the first holder of the association's medal for meritorious ser-

vices, and on more than one occasion, at congresses and special meetings, he received tributes of affection and appreciation tendered by his colleagues. His influence extended very far, but he wrote few medical articles, and those chiefly on ethics and the history of medicine. He was highly cultured, a good linguist, a keen controversialist but always a chivalrous opponent in debate.

PRAGUE

(From Our Regular Correspondent)

March 1, 1934

Conference on Preventive Medicine

The fourth National Conference of Preventive Medicine was held on February 1-4 at Karlova Studánka, a small watering place of Silesia. This congress is becoming an important institution for the promoting of public health measures in Czechoslovakia. Four main topics were on the program. The first dealt with a reform of the law on infectious diseases. The conference came to the conclusion that a law for combating infectious diseases should not be too specific and should contain only a frame for measures that might be filled in at subsequent periods in accordance with the progress of bacteriology and epidemiology. This is the main criticism of the law of 1913, now in force, which was modern at that time but became rapidly antiquated by progress in research in protective measures against infectious diseases. It was emphasized that means should be provided for the building up of a chain of bacteriologic laboratories, widespread immunization should become an integral part of the working program of the official public health machinery, and means should be provided from public funds from which expenses connected with isolation of patients, suspects and carriers could be defrayed.

The second main topic dealt with a plan for the reorganization of public health service, presented recently by Dr. Albert. This plan calls for the concentration of the public health services around hospitals. Health officers are inclined to become bureaucratic when they have no direct contact with a purely medical institution. Diagnostic facilities available in public hospitals are of immense value for the application of measures of social hygiene in case the hospital physicians are properly oriented toward preventive work. The conference came to the conclusion that the plan might be practical in places where the direction of the hospital is in the hands of physicians who have an equally balanced interest in public health and in curative medicine.

The third point of the conference dealt with the organization of maternity service. There is a general tendency for the concentration of confinements in public institutions. In spite of that, for a long time a great number of confinements will be in the hands of midwives. The main difficulty lies in a proper distribution of competent midwives. They flock to cities, while in rural areas, where usually the birth rate is high, there is a scarcity of them. The conference formulated recommendations according to which the country should be divided into small areas where a certain number of paid confinements would be guaranteed to the midwife. She would have her income either insured from private practice or assured from insurance funds and, in the case of the poor, from public funds. The conference, which was of a private character, had a large attendance of physicians, governmental representatives, lay representatives of the sickness insurance, and the legislature.

Discussion on Prevention of Conception

The question of the limitation of pregnancies through natural means was considered at a recent meeting of the Association of Czech Physicians. Owing to the high percentage of Roman Catholics in Czechoslovakia the so called Ogino-Knaus method of limiting pregnancies came to be advocated in the country.

The theory back of this method is that impregnation of the ovum is possible only during certain days of each monthly cycle. Prof. Antonín Ostrčil at this meeting declared that according to his experience there is no time in the intermenstrual period that could be definitely declared as the safe period. According to him, ovulation and the whole monthly cycle are governed by many factors, which make any regularity impossible. Ovulation is influenced not only by hormones but also by nervous factors, which intermingle freely and do not admit any reliable prediction. In the general discussion, the experiences of practicing physicians were presented who have tried this method and have failed in most cases. The discussion may be summarized in the conclusion that according to present knowledge the prevention can be assured with some reliability only through artificial means.

Professor Vymola Honored

The seventieth birthday of Prof. Charles Vymola was celebrated recently by the Czechoslovakian Otolaryngologic Association. He is the president of this body and the oldest active representative of this specialty in Czechoslovakia. He began lecturing on otolaryngology in 1902 and became professor of this subject in 1913. His early work was concerned with the etiology of infectious rhinoscleroma. Many of his papers are concerned with questions of therapy, and he has had wide experience with otosclerosis. He is the founder of systematic care for deafmutes in Czechoslovakia. He started a small institution for them in 1917, which he ultimately enlarged in 1926 into a magnificent institution, attached to which is a cooperative institution for graduates which assists them during their whole life. At the meeting, his effort for establishing this work in children's hospitals, and his work for the soldiers in the war, were described.

Rebuilding of General Hospital at Prague

The hospital facilities of Greater Prague are becoming again insufficient, in spite of the recent addition of a new city hospital. The reconstruction of the old general hospital of Prague where both the Czech and German faculties are located, has been considered. The main reason for delay lies in the fact that an effort was made to keep all the departments and clinics nearby for the benefit of medical students. A site was found about 8 miles from the center of the city, where the second internal clinic of the Czech university of Prague will be housed. When this institution is completed, a section in the general hospital in Prague will be razed and a new building erected for other hospital clinics. In a similar way the whole general hospital is to be reconstructed. The funds for the beginning of the project are available. The fact that medical students will not be from now on concentrated in one hospital represents a new principle.

Marriages

- HARRY ERNEST HEINITSH JR., Spartanburg, S. C., to Mrs. Annette Blake Franklin of Charleston, April 17.
LESTER WHITE BAIRD, San Jose, Calif., to Miss Helen Keshner of Woodriver, Ill., March 31.
CHARLES E. VERDIER, New Orleans, to Miss Wanda Hies of Sugartown, La., March 21.
CHARLES BARTON ETTER to Miss Frances Durham, both of Memphis, Tenn., March 27.
HENRY H. RUBIN to Miss Dorothy E. Liebling, both of Chicago, Dec. 31, 1933.
ROBERT TENNANT JR., New Haven, Conn., to Miss Dorothy Davis of Essex, April 7.
AARON E. GREENBERG to Miss Shirley D. Fink, both of Brooklyn, April 15.

Deaths

William Henry Welch [®] President of the American Medical Association (1910-1911), one of the deans of American medicine, for fifty years an inspiration in American medical education, died in Johns Hopkins Hospital, Baltimore, April 30 aged 84 years. Throughout his life he exercised an almost magical influence on those who worked with him. His eightieth birthday was marked by a world-wide celebration such as has been accorded to few indeed of the great leaders of American medicine. Innumerable medical honors were bestowed upon him.

Dr Welch was born in Norfolk, Conn., April 8, 1850. His father was a doctor, as were also four uncles. He entered Yale University at 16 years of age, and in 1870 at the age of 20, received the degree of Bachelor of Arts. Then he spent a year teaching Greek and Latin, after which he entered the College of Physicians and Surgeons in New York. Behaving, however, that he required further training in chemistry, he returned to New Haven for further work in the Sheffield Scientific School. After a year of such graduate work, Dr Welch again entered the College of Physicians and Surgeons, where he worked in the dissecting room and became assistant to the professor of anatomy. In 1874 he became intern at Bellevue Hospital, receiving the degree M.D. from the College of Physicians and Surgeons of Columbia University in 1875. Then in 1876 he departed for study abroad, arriving in Europe in that epoch-making period which marked the establishment of pathology and the beginning of bacteriology as medical sciences. At Strasbourg he studied under Waldeyer, Hoppe Seyler and von Recklinghausen. After this foundation in histology and physiologic chemistry he continued his work in pathology in Strasbourg and at Leipzig, at Breslau he worked on the heart with Cohnheim, and at Vienna he studied pathology with Chiari, neurology with Meynert and diseases of the skin with Hebra. He continued his work in Paris and in London and returned to the United States in 1878.

Beginning his practice in New York, he was invited to lecture in pathology in his alma mater and to undertake research in the Bellevue Hospital Medical College. When Johns Hopkins Medical School was established in 1884 he was called to the chair of pathology. It has been said that Cohnheim made the suggestion for his appointment. In the meantime the work of Robert Koch and of Pasteur had come prominently to medical attention so that Dr Welch left for another visit abroad, studying principally from 1884 to 1885 with Koch and Flügge. Since the Johns Hopkins Hospital was not opened until 1889 and the medical school until 1893, a period intervened during which the laboratory of Dr Welch was the center of medical study in Baltimore. It was with his advice that Osler, Halsted and Kelly were appointed to the staff. It was during this period also that Dr Welch made his most significant contributions to the science of medicine, doing research on animal diseases, infections and immunity, and gas gangrene. It was also in this period that he published books on "The General Pathology of Fevers," and on "The Pathology of Bacteria Infections and Immunity."

From this time on the name of Dr Welch appears much more significantly as an administrator and as an adviser in the field of preventive medicine and public health. It is significant that many of the young men who were associated with him in his early days eventually achieved great fame in the field of medicine. Such names as those of Councilman, Mall, Nuttall, Abbott and Bolton are found among the first of his students. With the establishment of the Johns Hopkins University School of Medicine came a great inspiration for the raising of standards

in American medical education. By his leadership Dr Welch stimulated advancement of research, hospital organization, medical education and public health. Perhaps his inspiration helped to make the pathologic laboratory the center of the modern hospital and the medical school.

By 1894 his repute, although he was but 44 years of age, had already grown so that honorary degrees were given to him and continued to be awarded to him for many years. He received the honorary M.D. from the University of Pennsylvania in 1894 and LL.D. from Western Reserve University in the same year. Yale conferred this degree on him in 1896, Harvard in 1900, Toronto in 1903, Columbia in 1904, Jefferson Medical School in 1907, Princeton in 1910, Washington University in 1915, the University of Chicago in 1916, the University of Southern California in 1930, and the University of the State of New York in 1930. He also received the degree of Doctor of Sciences from Cambridge in 1923, Western Reserve in 1929 and the University of Pennsylvania in 1930. Moreover, he was awarded the doctorate of the University of Strasbourg in 1923.

Dr Welch was professor of pathology in Johns Hopkins University School of Medicine from 1884 to 1916 and dean of the medical faculty from 1893 to 1898. Coincidentally with his

teaching position in pathology he was pathologist to Johns Hopkins Hospital. He became director of the School of Hygiene and Public Health from 1916 to 1926, and on his retirement from that office was made professor of the history of medicine and in 1931 emeritus professor. The Institute of the History of Medicine in Johns Hopkins University School of Medicine contains a medical library named in his honor.

Especially significant in the life of William Henry Welch was his immediate contact and guiding influence in many organizations associated with medicine for social, humanitarian or philanthropic purposes. Thus, he was president of the State Board of Health of Maryland from 1898 to 1922 and continued as a member until 1929. He was continuously president of the board of directors of the Rockefeller Institute for Medical Research, 1901-1933. He served as a member of the International Health Board and of the China Medical Board of the Rockefeller Foundation and as trustee of the Carnegie Institution. He was frequently consulted by the League of Nations and by many foundations having medical interests. His conspicuous achievements were recognized by election to the presidencies of

important organizations, including the Congress of American Physicians and Surgeons in 1897, Association of American Physicians in 1901, American Association for the Advancement of Science 1906-1907, the National Tuberculosis Association 1910-1911, the National Academy of Sciences 1913-1916, the American Social Hygiene Association 1916-1919, the National Committee of Mental Hygiene and many similar bodies.

When the United States entered the World War in 1917 he was commissioned Major in the Medical Reserve Corps, advanced to Lieutenant Colonel in February 1918 and to Colonel in July 1918, finally being made Brigadier General in the Officers Reserve Corps in 1921. He served principally as adviser in the Surgeon General's Office and in the organization of the special services of pathology and preventive medicine.

His honorary memberships included distinguished medical and sanitary organizations in England, Scotland, Ireland, Austria, Germany, Belgium, France, Italy and Switzerland. Moreover, the governments of many foreign countries recognized him by decorations which include those of Japan, Norway, Serbia and France as well as the United States government.

In the American Medical Association Dr Welch may be said to have begun his career as President of the Medical Chirurgical Faculty of the State of Maryland in 1891-1892. He was a member of the House of Delegates from 1902 to 1903 and served as a trustee of the Association from 1903 to 1909. This service culminated with the Presidency in 1910-1911.

WILLIAM HENRY WELCH, M.D., 1850-1934

The occasion of his eightieth birthday was celebrated by distinguished gatherings not only in Washington but in many of the capitals of the world. Herbert Hoover, former President of the United States, made an address which was broadcast over the radio, and celebrations were held in scientific institutions. An exhibit of his medical writings in the John Crerar Library in 1930, on this occasion, included more than 350 articles. These were collected in three memorial volumes.

The influence of Dr. Welch on American medical education during the last twenty years is impossible to overestimate. Certainly, he played an important part in the development of the full time system of teaching in the clinical branches, in the establishment of schools of public health and hygiene, and in stimulating great financial contributions for the advancement of preventive medicine and public health. So significant was this influence that even during the last five years of his life when he was ill much of the time, his very spirit dominated the minds of many of those who had been associated with him. No doubt, much of his great influence was due to the remarkable gentility of his character. His personality was sparkling, his wit noted, and the twinkle of his eye characteristic. His friendships were abiding and he gave freely of himself to almost every demand that came upon him. His culture was notable and his familiarity with the literature, music and art of his time equal to that of many experts in all of these fields. Such men do not come often in any phase of human life, but when they do appear the humanistic quality of their greatness brings them universal recognition.

Frederick Newton Gisbourne Starr, Toronto, Ont., Canada, University of Toronto Faculty of Medicine 1889, professor emeritus of clinical surgery at his alma mater, general secretary, 1893-1901, member of the executive council, and in 1927 president of the Canadian Medical Association, counselor of the College of Physicians and Surgeons of Ontario 1907-1911, in 1926 president of the Toronto Academy of Medicine, president of the Royal College of Physicians and Surgeons of Canada, 1931-1933, formerly vice president of the British Medical Association, fellow and past vice president of the American Surgical Association and the American College of Surgeons, served in France as a major with the Royal Army Medical Corps during the World War and was created a commander of the military division of the Order of the British Empire, for many years consultant on the staffs of the General Hospital, St. John's Hospital, Western Hospital and the Hospital for Sick Children, contributed numerous articles to the various medical journals, aged 66, died, April 21.

J. George Dempsey, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1899, member of the Louisiana State Medical Society, assistant professor of preventive medicine and public health, Louisiana State University Medical Center, served during the World War, professor of clinical pediatrics, Loyola University School of Medicine, Chicago, 1919-1925, since 1920 state registrar of vital statistics, state board of health, visiting pediatrician to the Touro Infirmary, 1899-1907, senior visiting surgeon to the division of gynecology and obstetrics, State Charity Hospital, 1907-1917, aged 61, died, February 4 of arteriosclerosis.

Edward Philip McCormac, New Orleans, University of Texas School of Medicine, Galveston, 1920, member of the American Urological Association, fellow of the American College of Surgeons, instructor in urology, Tulane University of Louisiana School of Medicine, visiting surgeon to the Charity and French hospitals, on the adjunct staff of the Hotel Dieu Hospital and the Touro Infirmary, aged 37, was found dead, March 3.

Edward Joseph Mahoney, Springfield, Mass., Georgetown University School of Medicine, Washington, D. C., 1895, member of the New England Surgical Society, fellow of the American College of Surgeons, formerly on the staffs of the House of Providence and the City Hospital, Holyoke, surgeon in chief to the Mercy Hospital, aged 64, died, March 26, of hypertensive heart disease and cerebral hemorrhage.

Charles Ross Bullock, Major, U. S. Army, retired, Atlanta, Ga., Atlanta School of Medicine, 1907, served during the World War, entered the medical corps of the regular army in 1920 as a captain and retired as a major in 1929 for disability in line of duty, city physician, aged 51, died, March 24 in a local hospital, of coronary occlusion and arteriosclerosis.

Armin Nettle, New York, Eclectic Medical College of the City of New York, 1901, Long Island College Hospital, Brooklyn, 1910, member of the Medical Society of the State of New York, on the staff of the Manhattan Eye, Ear and Throat

Hospital, aged 57, died, February 19, of arteriosclerosis and coronary thrombosis.

George Alexander Knowles, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1894, member of the House of Delegates of the American Medical Association, 1921-1922, assistant director of health, formerly on the staff of the Misericordia Hospital, aged 65, died, April 11, of heart disease.

John Oliver McDonald, Trenton, N. J., Columbia University College of Physicians and Surgeons, New York, 1909, for many years member of the state board of health, aged 49, died, March 29, in the Columbia Presbyterian Medical Center, New York, of embolism of the lung, following an operation.

Reverdy Edgar Hughson, Orient, Ohio, McGill University Faculty of Medicine, Montreal, Que., Canada, 1896, served during the World War, first assistant physician at the Institution for Feeble-minded since 1926, aged 62, died, March 24, in the Grunt Hospital, Columbus, of colitis and pneumonia.

Walter P. Mattox, Sullivan, Mo., Beaumont Hospital Medical College, St. Louis, 1897, member of the Missouri State Medical Association, president of the Franklin County Medical Society, aged 63, died, March 22, in the Missouri Baptist Hospital, St. Louis, of cerebral hemorrhage.

William S. Erdman, Buckingham, Pa., Medico Chirurgical College of Philadelphia, 1896, member of the Medical Society of the State of Pennsylvania, past president of the Bucks County Medical Society, aged 64, died, April 7, in the Lankenau Hospital, Philadelphia, of heart disease.

Frederick Ellsworth Lambert, Jersey City, N. J., Long Island College Hospital, Brooklyn, 1894, past president of the city board of health, past president of the Hudson County Medical Society on the staff of the Christ Hospital, aged 70, died, March 1, in Bryonne, of heart disease.

Thomas Fred Jackson, Dade City, Fla., Atlanta Medical College, 1914, past president and secretary of the Pasco County Medical Society, served during the World War, for many years proprietor of a hospital bearing his name, aged 45, died, March 21, of carcinoma of the leg.

Harry Willis Sutcliffe, Beverly Hills, Calif., Chicago Homeopathic Medical College, 1892, College of Physicians and Surgeons of Chicago, 1894, Rush Medical College, Chicago, 1895, formerly a practitioner in Chicago, aged 66, died, March 31 of arteriosclerosis.

John D. O'Garra, Urbana, Ohio, Starling Medical College, Columbus, 1903, member of the Ohio State Medical Association, president of the Champaign County Medical Society, aged 53, died, February 18, following an operation for gall stones.

Knox Bacon, San Diego, Calif., University of Minnesota College of Medicine and Surgery, Minneapolis, 1894, member of the Minnesota State Medical Association, served during the World War, aged 69, died, April 7, of coronary thrombosis.

Michael Joseph Costello, Asheville, N. C., Medico-Chirurgical College of Philadelphia, 1896, served during the World War, aged 68, died, March 21, in the U. S. Veterans Hospital, Oteen, of carcinoma and intestinal obstruction.

George Lucene Langworthy, Tyler, Texas, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, served during the World War, aged 55, died, March 31, of cardiorenal disease.

James William Kelly, Chicago, Hahnemann Medical College and Hospital, Chicago, 1899, Rush Medical College, Chicago, 1900, on the staff of the Roseland Community Hospital, aged 59, died, April 4, of heart disease.

William Henry Skene, Portland, Ore., Long Island College Hospital, Brooklyn, 1888, served during the World War, fellow of the American College of Surgeons, aged 67, died, March 30, in St. Vincent's Hospital.

John Joseph Mayercik, Danbury, Conn., University of Cincinnati College of Medicine, 1928, on the staff of the Danbury Hospital, aged 31, was drowned, Dec. 15, 1933, at Stratford, while duck hunting.

Augustus Dennis Pitts, Point Arena, Calif., Long Island College Hospital, Brooklyn, 1892, aged 71, died, March 25, of cirrhosis of the liver.

Dennis Neville, Hildreth, Neb., Illinois Medical College, Chicago, 1900, aged 73, died, March 5, of lobar pneumonia.

James S. Koontz, Johnstown, Pa., College of Physicians and Surgeons, Baltimore, 1891, aged 75, died, January 15.

Bureau of Investigation

SLEEPY SALTS

Another High-Priced Saline Laxative

Seldom does there appear any element of originality in nostrum exploitation. Should some "patent medicine" concern appeal to public gullibility from a new angle with results that bring home the financial bacon, no time is lost by others in the same lines of business in imitating as nearly as possible the exploits of those that have struck pay-dirt in the exploitation of the ailing human.

The intensive radio advertising campaign that seems to have made "Crazy Crystals" such a financial success is probably responsible for the flooding of the market with innumerable other "crystals" and "salts," such as "Sane Crystals," "Calumet Crystals," "Certified Mineral Crystals," "Texas Mineral Crystals," and many more.

SLEEPY WATER

The public is now being bombarded with an advertising campaign for "Sleepy Salts," which are said to be put out by the exploiters of a mineral water, "Sleepy Water." A careless reading of the advertising might give one the impression that Sleepy Salts are the saline ingredients of Sleepy Water. Readers of THE JOURNAL with long memories may remember that there was published a brief editorial comment in the issue of November 18, 1916, under the title "Sleepy Water for Wide-Awake Doctors." This was at the time that Sleepy Water was being heavily advertised to the medical profession of Chicago under the claim that "This Highly Radioactive Water Cures Diabetes Bright's Disease, Many Other Ills." It was pointed out in the editorial comment that the exploiters of this nostrum were evidently familiar with the fact that such a claim as the one just quoted, if made on the trade package, would immediately subject the company to prosecution under the federal law, and that no such claims appeared on the trade package. Lying in newspapers and circulars while just as immoral, carries with it practically no risk of legal reprisal—thanks to our inadequate federal law. The same thing applies, of course, to lying over the radio, an art which has developed into America's most popular indoor sport.

The earlier claims for high radioactivity have apparently been dropped by the exploiters of Sleepy Water. Whether this is due to the fact that the claim is and always was false, as the water is not highly radioactive or whether the death of the industrialist, Mr. Byers, from the drinking of water containing in solution radium salt (not radium emanation) has caused the radium-water game to suffer a severe slump, is a question we cannot answer.

At this point the alleged composition of Sleepy Water should be a matter of interest. In the past sixteen years there have been different analyses published by the Sleepy Water Company of the water itself. The analyses are hopelessly at variance with each other. One analysis, said to have been made by "H. H. McCormack, Professor of Chemical Engineering, Armour Institute of Technology," gives the chief mineral constituents (parts per million) of Sleepy Water as follows:

Calcium sulphate	18.36
Sodium chloride	13.26
Aluminum sulphate	10.28
Ferrous sulphate	6.84

Another analysis distributed by the Sleepy Water Company and said to have been made by "S. H. Herzfeld, S. B. S. M. Chief Chemist" gives the following figures, also in parts per million:

Sodium bicarbonate	27.40
Sodium carbonate	23.50
Sodium chloride	13.20
Calcium carbonate	11.15

Apparently one can pay his money and take his choice!

SLEEPY SALTS

Within the last year or eighteen months the Sleepy Water concern has come to the public with its product Sleepy Salts. Part of the advertising consists of a newspaper-size eight-page broadside called the *Hot Springs News* which is distributed

free by the Sleepy Water Company "which has its headquarters at Hot Springs, Ark., and its 'midwest headquarters' in Chicago. In the *Hot Springs News* the public has been told:

Because of the high cost of shipping quantities of Sleepy Water the Sleepy Water Company sought for many years to find a way in which a so-called spa or health resort water could be brought directly into the home in a new form. Sleepy Salts synthetically developed after much painstaking effort from earthly minerals are proving unusually successful and of tremendous value in this direction.

Elsewhere, in discussing the alleged composition of Sleepy Salts, the same advertising broadside states:

Sleepy Salts are a synthetic proximation of the minerals found in the famous Sleepy Water.

Sleepy Salts the natural mineral combination.

These [Sleepy Salts] are a balanced synthetic formula which combine the pure earthly minerals in a scientific combination.

The trade package has given no information that has any meaning on the subject of composition. A circular which comes with the package has stated:

The formula for Sleepy Salts is very interesting and consists of the scientifically balanced combination of ingredients of the mineral elements which are found in the waters of the famous spas and health resorts of Europe and this country.

The same circular, under the heading "Your Doctor Will Approve," states:

For the benefit of physicians we are glad to send them the balanced formula of Sleepy Salts. The various styles of Sodium, Potassium and Magnesium that are balanced in Sleepy Salts promote the elimination of waste.

While the phrase "various styles of Sodium, Potassium and Magnesium" is wholly without meaning, the public doesn't know it and it presumably makes good advertising. A physician wrote to the Sleepy Salts concern in the middle of March, 1934, asking for the 'balanced formula.' The letter was addressed to the Sleepy Water Company at Chicago, an address that appears on the cartons of the package sold, at least, through the middle west. After some delay he got an answer from the Chicago office stating that as the city in which the physician lived "is the home of a number of reducing preparations," the Chicago branch had sent his letter to the home office at Hot Springs "so that they could decide whether the full information should be given." Apparently the home office decided against sending the information, as up to the date of writing the physician had received no reply.

The Bureau of Investigation of the American Medical Association wrote to the Sleepy Water Company at the home office, Hot Springs, Ark., asking them whether they cared to send the Bureau the formula for Sleepy Salts, as has been claimed they would do in their trade package. A letter was duly received, most of which was devoted to expressing complimentary opinions regarding the Bureau and its work. The statement was then made:

Sleepy Salts is composed of 35 per cent sodium citrate and citric acid and the balance potassium chloride, potassium sulphate, sodium sulphate, magnesium sulphate and sodium chloride.

After acknowledging the receipt of the company's statement another letter was received stating that the figure 35 in their statement should have been 15. In their second letter the company also stated: "We are not supplying at this time the exact quantities of each ingredient." So much for the claim of the concern that they would send 'the balanced formula of Sleepy Salts' to physicians.

In October, 1933, the federal officials of the Food and Drug Administration made two seizures of Sleepy Salts, charging that they were misbranded in violation of the National Food and Drug Acts. No claimant appeared for either seizure and the court held that the product was misbranded and ordered that the goods be destroyed. The government chemists analyzed Sleepy Salts and reported finding the following ingredients:

Sodium sulphate (Glauber's salt)	48.5 per cent
Magnesium sulphate (Epsom salt)	35.3 per cent
Sodium chloride (table salt)	10 per cent

The government's findings have been essentially confirmed by a report received from the U. S. Chemical Laboratory. In other words, Sleepy Salts according to these analyses is essentially a mixture of Glauber's salt and Epsom salt. Yet from the statement furnished the Bureau of Investigation by the Sleepy Salts concern itself one would naturally assume

BUREAU OF INVESTIGATION

JOUR. A. V. A.
MAY 5 1934

that sodium citrate and citric acid were the important ingredients. The actions of the Sleepy Salts exploiters are characteristic of the 'patent medicine' fraternity. A lack of frankness, false statements, and an apparent inborn desire to deceive seem to characterize the nostrum interests.

The exploiters of Sleepy Salts are under no legal obligation—although there certainly is a moral obligation—to give either the medical profession or the public any information regarding the composition of their nostrum. Yet they state definitely that they will send physicians 'the balanced formula' of the mixture. If they were honestly willing to do this, there was no reason for any hesitation in furnishing the Bureau of Investigation or any physician with that information. If such information were being sent frankly and truthfully to any physician who would write them, as the statement in the package indicated it would there could be no secrecy about the composition nor any reason for stating as they did in their letter to the American Medical Association that knowing the Bureau's attitude they felt that they would be justified in refusing to send information.

Needless to say the exploiters of this saline would not think of overlooking an obvious bet in advertising this product as an 'obesity cure'. From the popularity of the lady who suggests that we come up and see her some time and the fact that the fake "bust developers" are again being advertised, it is apparent that curves really are coming back. Yet it is a fact that many a woman still looks upon the hermaphrodite as typifying the ideal feminine figure. Hence the ease with which some women may be humbugged through the sale of alleged shortcuts to the sylph figure.

How to Lose Fat Quickly

Without Drugs
Without Starving
No Violent Exercise

Eat Big Meals, Yet
See Inches Melt Away
Fat Goes Fast Or No Cost

FEELS LIKE A
"NEW" WOMAN

Lose Ugly Fat—
But Build Health!

Some recent advertising of Sleepy Salts

The entire back page and no small proportion of the other pages of *Hot Springs News* are devoted to the alleged 'obesity cure' virtues of Sleepy Salts. Fat women are urged to 'Eat Big Meals, Yet See Bulky Inches Melt Away Fast'. After the money has been paid the purchaser of Sleepy Salts finds that the diet of which she may eat all she wants is a limited and hopelessly unbalanced one. She is told it is best not to eat any bacon, ham, pork, sugar, candy, pastry, cheese, cream, butter or potatoes and to eat little of white bread, milk, macaroni, parsnips, carrots, raisins, figs, onions, etc.

But the full-page advertisement in *Hot Springs News* must be very appealing to those women who persist in eating too much and exercising too little but crave a willow-like figure. They are told, for instance, that Alice Brown of Chicago not

only likes the taste of Sleepy Salts, but she has lost 39 pounds since she started using it two months ago, that Georg. Rose Carson of Chicago, lost 24 pounds in thirty days, that without getting any results, took Sleepy Salts for two months and lost 32 pounds that Betty Greines, a Chicago stenographer, lost 33 pounds—reduced from 203 to 170—in 23 days! The same advertisement declares Sleepy Salts "A combination of vital health salts of earthly metals blended together to produce the quickest safe results in reducing excess fat."

SLEEPY WATER
This Highly Radio-Active Water
CURES
Diabetes—Bright's Disease—Many Other Ills

Radium is the greatest discovery of the age! Its Miraculous Powers to cure the bodily ailments of Mankind have astounded the Medical World! Its Lifegiving Force de Leon's dream of an Elixir of Life nearly realized.

This is the way that Sleepy Water used to be advertised. Not on the trade package of course which would have subjected it to seizure under the Food and Drug Act but in the collateral advertising that is virtually free from legal control.

But it is not only obesity that Sleepy Salts will cure learn—again from *Hot Springs News*—that Sleepy 'Calms Nervousness,' 'Clears Bad Skin,' 'Rids Gas Pain,' 'Hits Rheumatism,' 'Stops Backache' and 'Relieves Constipation.' Yet in spite of these wonderful therapeutic possibilities and the further fact that the chief ingredients of the product are Glauber's salt and epsom salt, we are told that 'Sleepy Salts contains no drugs!'

Every 'patent medicine' must, of course, have a testimonial from a physician. Sleepy Salts is no exception. The *Hot Springs News* advertising broadside screams in huge black face type spread across the entire page: 'Doctors Acclaim Health Water.' Then in a subhead: 'Doctors Send Thousands of Men and Women to Hot Springs, Arkansas, to Correct Faulty Elimination of Kidneys and Intestinal Tract. Say This is Root of Most Common Ailments.' Technically, of course, this claim is correct. Used as it is by the Sleepy Water outfit, it is misleading. Sleepy Water itself does not come from Hot Springs, Ark., but from a location in the same general territory.

Sleepy Salts with which this advertisement deals, being a synthetic mixture originates, presumably, in a factory. It is significant in this connection that prior to December, 1933, the carton of this patent medicine carried in letters nearly an inch high the words 'SLEEPY SALTS' with the word 'brand' between them in letters so small as to be nearly undecipherable. Today the label carries the words 'SLEEPY BRAND SALTS' in large letters all of the same size. Furthermore, the picture of the Sleepy Water Company building at Hot Springs, Ark. that formed part of the carton up until last December has disappeared. In this way the carton which comes within the purview of the National Food and Drugs Act has been so modified as to remove the cruder misrepresentations in the matter of making the public believe that Sleepy Salts bears some relation to Sleepy Water.

In spite of the impression given that doctors generally recommend Sleepy Salts we have found in the advertising just one doctor who can be credited—if it is a credit—with a testimonial for this crude patent medicine. This doctor is Clarence W. Flint MD of Chicago. Dr. Flint is described by the Sleepy Salts concern as a well-known physician. The records of the American Medical Association show that Dr. Flint was born in 1890 holds a diploma from the Chicago College of Medicine and Surgery 1917 an Illinois license of the same year is not a member of the Chicago Medical Society or, of course of the American Medical Association. A search of medical journals during the past seventeen years fails to show that Dr. Flint has contributed anything to contemporary medical literature.

Summed up then it appears that Sleepy Salts has been so advertised as to lead the public to believe that it is a 'synthetic proximation' of Sleepy Water, which in the past according to

the advertising, has been given various compositions. The company, when written to asking for the information regarding the composition of Sleepy Salts, which their advertising claims they will send, states that Sleepy Salts is about 15 per cent sodium citrate and citric acid (neither of which substances of course, is to be found in any natural spring water). Government analysis shows that Sleepy Salts, like the great bulk of the high priced and extravagantly exploited salines on the market today, is essentially "horse salts" (sodium sulphate—Glauber's salt), with a proportion of epsom salt added. In other words, in buying Sleepy Salts one pays 75 cents for three and a half ounces of what is essentially a mixture of Glauber's salt and epsom salt. For this same amount one could buy enough Glauber's salt to last a year, but he would not be paying for the high-priced ballyhoo that goes with the exploitation of Sleepy Salts.

The high-pressure advertising campaign for saline cathartics, while doubtless bringing in vast sums of money to newspapers and broadcasting stations, is a pernicious influence on the public health. Few medicaments are more generally abused than are the salines. Fantus has well pointed out that these salts "belong among the habit-forming drugs and are responsible for a large proportion of cathartic habit." The same authority has called attention to the fact that such salines "are occasional accessory causes of death from ileus and appendical and other forms of peritonitis." A fact only too well known to the surgeon.

But the "patent medicine" industry is founded on the thesis that in order to sell secret mixtures of cheap and common drugs under extraordinary claims and at fantastically high prices, it is necessary to persuade well people that they are sick. Under our present inadequate Food and Drugs Act they can do this with impunity for it is only lies on or in the trade package that are subject to the penalties of that law. The advertising pages of newspapers and the radio programs of the broadcasting stations are subject to no such control—which doubtless explains the campaign of misrepresentation and vilification on the part of many supposedly reputable newspapers and magazines against the proposed extension of the National Food and Drugs Act to cover collateral advertising.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

DERMATITIS VENENATA

To the Editor—I have a patient a woman aged 44 who had a rash with small blebs beginning over the left leg and spreading over the entire surface of the body including the scalp. The local symptoms itching and burning were almost intolerable. The Wassermann test has been negative on several occasions at the time and since. There was no fever. This occurred in July 1932. In June 1933 she had a similar attack which began on the right elbow. Both of these attacks were so severe that the entire skin was involved the patient having new skin over the entire body. The face was intensely swollen. The patient had to stay in bed from four to five weeks on each occasion. She also lost two or three fingernails at these times. On the first occasion she had been to the southern part of Alabama. The last time she had not been away from town. I made a diagnosis of poison ivy dermatitis in July 1932 but did not give her the extract. I cautioned her to avoid all places where she might come in contact with this plant after the first recovery and also to avoid touching Coral vines which she has around her home here in town. She says that she did not come in contact with any vine the last time. I would try some of the skin tests but have been afraid to do so because of her marked susceptibility. Do you think it safe for me to do this without starting the trouble from my tests? If she should have another attack do you think that I would be warranted in giving her the poison ivy extract if I should find her positive for this reaction? Should I use it as a preventive? Please omit name for this reaction? M D Alabama

ANSWER—The symptoms and result of physical examination of this patient would seem to warrant the diagnosis of a dermatitis venenata probably due to the oleoresin of poison ivy (*Toxicodendron radicans*). However there are other plants such as sumach, poison oak and primrose (*primula*) which may be responsible for the symptoms. The leaves and oil from other plants, such as ragweeds, burweed, marsh elder and chrysanthemums have also been incriminated. The excitant of poison ivy is an oleoresin that is not toxic for lower animals and is probably

not an antigen. The vesicles may be produced experimentally by the application of the excitant to the uninjured skin.

Dermatitis venenata from these plants constitutes an example of contact dermatitis and is markedly different in several particulars from the ordinary allergic or atopic eczema. In allergic conditions of the skin, such as the eczema in children due to the eating of eggs, the usual high percentage of positive family history occurs. One gets positive skin tests by either the scratch or the intradermal method, and observes the positive transfer phenomena as elaborated by Prausnitz and Kustner. On the other hand, patients sensitive to poison ivy show no evidence of hereditary influences. Fully 60 to 70 per cent of all persons are susceptible to poison ivy. The intradermal injection of poison ivy extract does not give the usual characteristic wheal, provided none of the substance has been left in contact with the surface. Furthermore, no sensitizing bodies have been found in the blood of even the most susceptible persons, and the passive transfer test is therefore negative. Poison ivy dermatitis is no more common in allergic individuals than it is in normal persons.

From the foregoing facts it can be readily seen that the ordinary cutaneous or intracutaneous tests are not indicated in cases of poison ivy. Contact or patch tests, however, are distinctly indicated although great caution should be used because of the possibility of lighting up a dermatitis, which may last for many weeks. If the diagnosis is reasonably certain it would probably be better not to make a patch test with poison ivy in this particular patient because of her great susceptibility.

The fact that the patient did not touch the vines the last time is no proof, because it is well known that contact is not necessary. The more susceptible individuals are affected by the amount given off in the air.

Treatment is indicated in cases such as these and the susceptibility to poison ivy usually is greatly lessened by injections of the extract. These injections can be given both prophylactically and during an attack. They will usually shorten the duration of the attacks of dermatitis.

TOXICOLOGY OF SODIUM NITROPRUSSIDE

To the Editor—Will you kindly let me know the toxicology of sodium nitroprusside? Have deaths been reported due to nitroprussides? The double cyanides are apparently nontoxic especially in neutral or alkaline menstrua though in conjunction with acid the CN group may be freed to do its deadly work (Holland J. W. A Textbook of Medical Chemistry and Toxicology ed 4 Philadelphia W. B. Saunders Company, 1915). Neither Taylor (1928 edition) nor Holland nor Witthaus (Manual of Toxicology ed 2 London Bailliere Tindall and Cox 1911) quotes any specific case of nitroprusside (nitrosoferricyanide) poisoning though uncommon deaths due to the other metallocyanides such as potassium ferrocyanide are referred to. I am giving short notes of a case of accidental fatal poisoning with sodium nitroprusside. A child aged 3 years had a few small crystals three or more of sodium nitroprusside given solid, by the mouth on a full stomach. The accident was discovered in an hour. The child had already started intermittent screaming and staggered while walking for water to drink half an hour after the swallowing of the crystals. An emetic was given immediately on discovery and a good quantity of undigested food was vomited. The child was immediately taken to a hospital and a subcutaneous injection of epinephrine was administered on the way. There it had an ounce of alba mixture an injection of atropine and a glycerin enema and within an hour of admission some of the antidote made up of potassium carbonate, ferrous sulphate and magnesium. Immediately afterward the child became unconscious. In the meantime oxygen inhalation was started soon supplemented by carbon dioxide supported by cardiac stimulants. Under the influence of carbon dioxide the respirations became deeper and the heart which earlier seemed to lose its tone regained it remarkably but only temporarily. Even before the child became unconscious the pupils were widely dilated. The tongue and mouth were moist to the end. After unconsciousness the child reflexly passed urine, rejected the earlier glycerin given by rectum and had a momentary convulsion of the limbs. Respirations went on unhampered till the end nearly four hours after the administration but the heart failed not responding to galvanic stimulation before the child died. I should be obliged for enlightenment on the following points: 1. Witthaus concedes the toxicity of the double cyanides when taken into a hyperacid stomach or in association with acids though cyanic effects were not obtained in experiments on dogs and guinea pigs. Could the optimum conditions for the splitting of the double cyanide have been obtained on a full stomach? 2. Could the administration of alkalis immediately on discovery of the accident within the first hour have stopped the disintegration of the double salt? 3. Could the emesis have promoted the freeing of the cyanogen by removing the neutralizing effect of a full stomach? 4. Could a stomach wash by hydrogen dioxide or potassium permanganate on admission into hospital have detoxicated the poison by oxidation into the relatively harmless oxamide (Holland)? 5. What might be the cause of the screams shortly after the swallowing of the crystals? Please omit name and address.

M D India

ANSWER—Sodium nitroprusside $\text{Na Fe}(\text{NO})(\text{CN})_5 \cdot 2\text{H}_2\text{O}$ represents dark red crystals which are soluble in 2½ parts of water. When heated with alkali it decomposes into ferric hydroxide, sodium nitrite and sodium ferrous cyanide.

Generally it is assumed that the formation of cyanogen, (CN)₂, is the most important factor in the toxic action of sodium nitroprusside. Hermann (*Arch f d ges Physiol* 39 419, 1886) reported that the blood and tissues of animals killed by this salt had a distinct odor of cyanogen. This was confirmed by Davidsolin (Inaug Diss, Königsberg, 1887), who failed, however, to identify cyanogen by means of chemical reactions. Cromme (Inaug Diss, Kiel, 1891) also concluded that the formation of cyanogen was the fatal factor in sodium nitroprusside poisoning. Fonces-Dixon and Carquet (*Bull soc chim* 29 638, 1903) take the same view, although they appear to have some doubt as to the validity of this assumption. Arntz (Inaug Diss, Kiel, 1897) apparently was the first to express doubts as to cyanogen being the toxic factor in nitroprusside poisoning. Bahrdur (*Chem Zentralbl* 75 248, 1904) showed that sodium nitroprusside is not a very potent protoplasmic poison and Garassini (*Boll d Soc med chir di Parma* 84, 1905) was able to demonstrate the presence of cyanogen in the blood and tissues of animals only when much larger than minimal fatal doses were administered. Johnson (*Arch internat pharmacol et therap* 35 480, 1929) gives an excellent review on this subject. He also was unable to demonstrate the presence of cyanogen as long as large but nonfatal doses were used, and only with excessive doses could he note the odor of cyanogen in the expired air. Johnson (1929) pointed out that the formation of nitroso compounds closely related to nitrites may be the determining toxic factor which was confirmed by the pharmacologic analysis of the action of sodium nitroprusside. He found that the oral administration of 5 mg per kilogram the subcutaneous injection of 0.05 mg per kilogram and the intravenous injection of as little as 0.001 mg per kilogram caused in cats, rabbits and dogs a prompt and definite fall of the blood pressure, accompanied by a slight acceleration of the heart, increase of the leg volume and decrease of the volume of the kidney. Anxious symptoms were produced by the administration of nitrites. The rapid onset of these symptoms indicates a rapid absorption. Equivalent doses of sodium cyanide (164 mg per kilogram) gave an entirely different picture, indicating that the action of sodium nitroprusside was not due to the liberation of cyanogen. The typical reactions observed in mammals after the administration of sodium nitroprusside were a dilatation of the peripheral blood vessels with simultaneous passive constriction of the renal vessels and acceleration of the heart on account of the reduction of the peripheral resistance. There was no effect on the cardiac muscle, which remained responsive. From these experiments it appears that neither the sympathetic nor the vagus or the central nervous system is involved primarily, but experiments with isolated organs (intestine and uterus) indicate that sodium nitroprusside has a direct muscular effect, differing from that produced by sodium cyanide.

The symptoms observed in mammals with fatal doses the minimal fatal dose with oral administration for rabbits being 250 mg per kilogram, are vomiting, rapid respiration, rapid pulse, general excitation, tremors, twitchings of the muscles, convulsions of the medullary type, mydriasis (prior to the arrest of the respiration), cyanosis, collapse and cardiac arrest. The persistent low blood pressure results in anemia of the brain, causing finally cerebral paralysis and depression of the heart. Since death may be postponed by artificial respiration, asphyxia must be considered the main cause of death. The action of sodium nitroprusside, therefore, is nearly identical with that of sodium nitrite, with the difference, however, that the former is more potent and less apt to form methemoglobin.

Animal experiments indicate that the treatment with intravenous injection of dextrose or colloidal sulphur are ineffective, that cardiac stimulants, such as caffeine and digitalis, have little value, and that the injection of epinephrine in 6 per cent acacia or epinephrine have only temporary effect.

The symptoms observed in the present case agree fairly well with those reported by Johnson for animals. In the light of the pharmacologic observations it appears that from the therapeutic measures used in this instance only the use of emetics, the injection of epinephrine hydrochloride and the inhalation of oxygen and carbon dioxide would have been of therapeutic value.

As to the questions submitted for answering it appears that

1 It is quite possible that a full stomach may favor the formation of nitrite-like compounds, on account of the neutralization of the hydrochloric acid by the ingesta.

2 The administration of alkalis presumably would favor the formation of such compounds.

3 Emesis has presumably no effect on the decomposition.

4 Lavage of the stomach with oxidizing agents probably might have been beneficial by oxidizing the nitrite to nitrate.

5 The cause of the screams may have been the distress caused by the low blood pressure.

ROENTGENOLOGIC ECONOMY AND PAPER X-RAY FILMS

To the Editor—As a member of the American Medical Association and a specialist of roentgenology for many years I would greatly appreciate it if the Association would investigate the matter of the mass production of paper x-ray films which I believe is fostered by the National Tuberculosis Association. May I refer you to the recent editorial published in the December issue of *Radiology* entitled "Falsely Roentgenologic Economy." The idea of a general roentgenologic survey for tuberculosis is to be commended but the methods used bespeak of good salesmanship rather than actual scientific knowledge. It is a step backward instead of a step forward in roentgenologic diagnosis.

CHARLES W. PERKINS MD Norwalk, Conn

ANSWER—The paper x-ray films used for mass production first appeared in 1931 when they were produced by the Powers Photo Engraving Company in response to a demand from the Queensboro Tuberculosis and Health Association for a film at low cost which could be used in making x-ray records of the chests of 25,000 children every year for five years. This was intended purely as a study, not only of the incidence of lesions but also of the changes that occurred in these lesions over a five-year period. The Powers company produced an emulsion that could be used on paper. Even after a satisfactory emulsion was developed, which reduced the cost, the task of exposing by the usual method x-ray films of the chests of 25,000 children annually was too slow. Devices were then added to the x-ray equipment which reduced the time of operation so much that from 500 to 1,000 exposures of chests could be made in a single day. A special device was then perfected for developing the large rolls uniformly and quickly. In order to prevent waste of time in handling, a special viewing cabinet was improvised which would slowly unroll the film so that each picture could be interpreted in the shortest possible time.

The booklet to which the editorial in *Radiology* refers was found on investigation to be the report of a committee appointed by the late Alfred Henry of Indianapolis when he was president of the National Tuberculosis Association. This committee consisted of twelve men and women from various parts of the United States, ten of whom were physicians. The report of the committee was prepared after much investigation, numerous meetings and considerable deliberation. The members of the committee were not prejudiced for or against the various subjects which they presented in their report. They attempted to present the subjects in the light of the best knowledge of the time. On further investigation, one learns that neither the board of directors nor the executive committee of the National Tuberculosis Association has taken any formal action concerning paper films but they have expressed their sympathetic interest in the development of the experimental work going forward along this line. The opinion of the National Tuberculosis Association is one of belief in the effective usefulness of the paper film when used by those who have given it special study, particularly in comparison with transparent films of the same patient. Since the paper film is viewed by reflected rather than transmitted light, it requires the exercise of more trained discrimination on the part of the reader and implies an expert knowledge of the variations which could not be expected of the average interpreter. The National Tuberculosis Association has been impressed by a good many careful tests, which have shown that in expert hands variations in judgment amount to such an exceedingly small percentage as not to vitiate the value of the films when used in taking a large series of cases. Their undoubted economy and the speed with which they can be used to examine large groups are points definitely in their favor. Therefore it is obvious that the National Tuberculosis Association has not fostered the paper film but has kept an open mind and is in sympathy with the development of any method that will facilitate the diagnosis of a greater number of cases of tuberculosis.

One finds further that there now exist two distinct points of view concerning x-ray work. The one is held by those who limit themselves entirely to this field. They are deeply interested in refinement of technique such as increasing the speed of exposure so as to remove as much blurring from heart action as possible in order to reveal detail, all of which is laudable, and the past accomplishment of such effort definitely extended the possibilities of the x-rays in diagnostic work. This group is of the opinion that the use of any film that cannot be exposed with adequate speed to bring out as fine detail as is now seen on the celluloid film is a definite step backward.

The other view is held by those devoting their lives to chest diseases and other clinicians who are desirous of seeing large numbers of persons have the advantage of a x-ray film examination but who were unable financially to afford it at its previous cost. This group of workers insists that the x-ray film is only one part of an examination. Although they consider it an important part and all use it extensively, they point to its

limitations even when the latest equipment and the most recent celluloid film is used. They call attention to the fact that pulmonary tuberculosis begins in a microscopic way and that it usually exists for many months before it can be detected by the x-ray film, that is, before it is macroscopic. They call attention to the numerous reports of roentgenologists, which are indefinite, that is, the words "possible" and "probable" frequently occur. They also call attention to statements of pathologists, who have shown that in the childhood type of tuberculosis revealed at the postmortem table, x-ray interpreters failed to record any evidence of it in 75 per cent of the cases. This group objects to the view in the editorial in *Radiology* that only radiologists should interpret x-ray films. They are of the opinion that the interpretation of films should not be limited to a few but that all qualified physicians should make interpretations in their fields. To them it does not seem wise to limit any method of diagnosis to a few physicians expert in that particular field. This group also states that much of the refinement in technique with the celluloid film has developed in the past five years, yet radiologists of five years ago claimed considerable expertness in detecting minimal tuberculous lesions. Those who are expert in the use of the new paper film insist that it already reveals more detail than celluloid films did five years ago and that by its use they are now capable of detecting definite lesions as early as by the use of celluloid films.

CORONARY THROMBOSIS AFTER PREVIOUS HEART DISEASE

To the Editor—Recently at a clinical conference in a hospital in this city a case was presented in which the patient exhibited for a period of two years symptoms of intractable endocarditis ending in congestive heart failure whereupon a heart specialist was consulted who diagnosed coronary thrombosis. The patient died and unfortunately an autopsy was refused. I should like to know the frequency of thrombosis of the coronary artery in subjects previously exhibiting signs of cardiac disease as revealed by autopsy. This is an important question for cases have been reported in which only one attack occurred the patient eventually dying of something else. Other patients have had more attacks and these often were lifelong invalids. From my own observation I am of the opinion that it depends on the valve involved. The main coronary vessels are less often involved in mitral disease than the aortic or pulmonary and this is due to the propinquity of the origins of the huge vessels to the small purveyors to the heart muscle. The left is the one more frequently involved according to statistics this may be due to the fact that in this event death is usually instantaneous and an autopsy is necessary to ascertain the cause of death. Accurate statistics will not be arrived at until an autopsy is held after every death. It is well known that intercurrent infections cause thrombosis of arteries in diverse situations in those afflicted with endocarditis so why not the coronaries? I have searched through such literature as I have had access to and need some light on the following questions: What is the accepted probable etiology of coronary thrombosis? Is endocarditis regarded as a probable cause in some instances and if so what valves and in what proportions and ratio to cases of thrombosis not exhibiting previous cardiac disease? Gray states that the coronary vessels anastomose freely in the substance of the heart muscle. Our professor mentioned in the beginning of this query stated that there was free anastomosis of the coronaries in the fatty tissues surrounding them. Gray, in his description does not even mention fat as being present. He must have thought that it was negligible. In this as in many other instances in the march of progress Gray has served me rather scurvily and another idol of my early medical study I must regretfully turn away from to consult a progressive

THOMAS I O DRAIN MD Philadelphia

ANSWER—Thrombosis of the coronary arteries occurs quite frequently in cases that have previously shown evidences of cardiac disorder of some kind. Dr Max Hochrein in reviewing his cases of coronary thrombosis in the *Muenchener medizinische Wochenschrift*, Oct 20, 1933, states that 75 per cent showed either symptoms or signs of previous heart trouble or even of coronary disturbance.

Coronary thrombosis often appears without any previous warning but not as often as is supposed when the previous history is carefully considered. Coronary thrombosis often occurs in the course of mild intercurrent infections and may even occur during convalescence.

It is impossible to enter into a discussion of the probable etiology of coronary thrombosis. Nothing definite is known. It cannot be merely a function of coronary sclerosis for coronary sclerosis affects the two sexes almost equally while coronary thrombosis is much more prevalent in the male. The etiology is a matter of debate and there is no accepted theory. If the pathologic changes following an old rheumatic carditis are considered as endocarditis coronary thrombosis does occur rather frequently in such cases. It is not especially frequent in an acute bacterial endocarditis although thrombosis and emboli involving the coronaries do occur in such conditions.

Coronary vessels anastomose freely in the substance of the heart muscle these anastomoses increasing with age. There is also some increase in the collateral circulation with age.

There are many vessels entering the myocardium from the subpericardial fat and of course this supply also increases with age, with the progressive increase of subpericardial fat. This is discussed by Lewis Gross in "The Blood Supply to the Heart," published by Paul B Hoeber. Gray should by no means be displaced as the idol of one's early medical study, as so much detail could hardly be expected in one volume.

TREATMENT OF PRURITUS ANI

To the Editor—I am treating several persons for pruritus ani. I have been using an ointment that contains picric acid and benzocaine. I am informed that some of these cases at least are caused by epidermophytosis. I would appreciate it very much if you could suggest some treatment that would eventually lead to a permanent cure. Thus far I have been able only to treat the disease symptomatically.

D E CAMP, MD Farmersburg Iowa

ANSWER—The etiology of pruritus ani is complex. Among the causes are:

- 1 The irritation of even the slight amount of fecal matter not removed by dry toilet paper
- 2 Ringworm or yeast infections
- 3 Bacterial infections, such as by the colon bacillus or *Streptococcus faecalis*
- 4 Animal parasites, pinworms or other intestinal worms or amebae
- 5 Local ailments, fissures, hemorrhoids, fistulas, skin tags, polypi or spasm of the anal sphincter
- 6 Intestinal disease, cryptitis, proctitis, colitis
- 7 Intestinal stasis, causing fermentation, absorption of toxins and irritation of the anus by hard feces
- 8 Liver disease, cholecystitis, cirrhosis, carcinoma
- 9 Genito-urinary disease, nephritis, cystitis, prostatitis, urethritis, vesiculitis, endometritis
- 10 Anemia, diabetes, exophthalmic goiter, the menopause, pregnancy
- 11 Neuroses
- 12 The results of scratching, eczema, lichen simplex chronicus

The treatment should be directed to correction of the cause, if that can be determined. In many cases, careful cleansing after each stool with a soft cloth or soft toilet paper, wet with water or boric acid solution, will stop the itching. If this is not entirely successful, an antipruritic ointment, such as compound resorcin ointment, can be applied after cleansing and whenever a paroxysm of itching occurs. On no account should the patient yield to the temptation to scratch. Rough or tight clothing should not be worn and the patient should not sit too long at a time. The generous use of talcum powder after the cleansing helps to counteract the tendency to maceration.

Ringworm or yeast infection can be determined by collecting scales or macerated epithelium treating it for a time with 10 per cent potassium hydroxide solution, and examining with the high dry lens, or by culture on sugar mediums, with incubation at room temperature for a week. If such infection is found a weak Whitfield ointment can be used, 1 per cent salicylic acid and 2 per cent benzoic acid in ointment of rose water, or, if the parts are much macerated, painting them once or twice daily with 1 per cent solution of potassium permanganate.

In all cases, hot foods and condiments, rich foods and sweets should be avoided, and care should be taken that neither constipation nor a fluid bowel movement occurs. Fissures can be painted with silver nitrate solution, from 2 to 20 per cent, once in several days. The parts may be painted once a day with compound tincture of benzoin or the following:

	Gm or Cc.
Tannic acid	13
Alcohol	
Glycerin	aa 15.0
Water to make	120.0

Heat may be applied as douches, sitz baths, hot compresses or hot air douches.

Autogenous vaccines are held in esteem by some authorities. Alkali bromides by mouth may be necessary for some patients, and some may need more expert psychotherapy than can be furnished by the general practitioner. Injections of the patient's own blood from 5 to 20 cc, given intramuscularly once every five days may be helpful.

When the cause cannot be removed and milder methods fail radiotherapy can be resorted to with fair assurance of relief. One fourth erythema dose of unfiltered or mildly filtered roentgen rays are given once a week until the itching ceases or until eight such doses have been given. It is not advisable to exceed this dosage. Care must be taken that the adjacent surfaces of the buttocks do not receive too great a dose.

Surgical methods have long been in use, but the old method of dissecting away the skin about the anus in order to cut the nerves is out of favor, for the nerves regrow and the itching returns in a large percentage of cases. The injection of 95 per cent alcohol under general anesthesia, 0.1 or 0.2 cc in each place, just under the skin, the injections about one-fourth inch apart over the whole area, is more successful, sometimes affording relief for years.

MENINGITIS

To the Editor —In May 1933 J.S. a boy aged 10, complained of persistent headache vomiting photophobia stiff neck and back and retraction of the head with persistent deviation to the left. The past history was essentially negative except for the usual disorders of childhood. The syndrome came on gradually following a swimming expedition. The first attack occurred about four years ago and was followed by nearly ten similar attacks at average intervals of about three months. The vomiting is projectile and he has a fever of from 100 to 101 F. gradually declining to normal over a period of about one week. His mother states that there is usually a skin rash on the face accompanying each attack and in the May 1933 attack when I first saw him, this was a typical herpes zoster on the tip of the nose and upper lip. At that time also physical examination was negative except for the complete picture of meningism. The reflexes are all entirely normal except a suggestive Kernig's sign. The urine is normal. The white blood cells number 13,750. The red blood cell count is normal. The differential count is polymorphonuclears, 76 per cent small lymphocytes 22 per cent, large lymphocytes 1 per cent, eosinophils 0.5 per cent, basophils 0.5 per cent. The eyegrounds and pupils are normal. The abdomen and rectum are normal. The spinal fluid is under increased pressure and clear. The cell count is normal. The colloidal gold curve, Kahn test, albumin, globulin and sugar are normal. The blood Kahn reaction is negative. The patient gradually recovered and he had no further trouble until last week in a scuffle at school he was struck over the back of the neck. The entire syndrome is delineated established itself. The neck and back are stiff but not markedly retracted. All examinations are negative except for fever of 99.6 F. a left sided positive Kernig sign and a suggestive left sided positive Babinski reflex. Blood and spinal fluid studies have not as yet been done this time. He is improving greatly under a low fluid intake and hypertonic high enema regimen. This time also he has the recurrent herpes over the bridge of his nose. He is a very intelligent youngster and I would greatly appreciate a discussion of his case with suggestions for investigation. I may say that there are no paralyses partial or total, and no nerve interference as evidenced by loss of pain and temperature, joint and tendon or tactile properties. Please omit name.

M.D. Michener

MD. MICHIGAN

ANSWER—The significant points in the query are the recurrent attacks of meningeal symptoms, with recovery after an attack of one week's duration. The condition described corresponds to Quincke's description of meningitis serosa. The correspondent states that he believes this condition to be due to an increase of intracranial fluid in the subpial spaces and within the ventricles, and that each attack is due to an acute increase of intracranial fluid characterized by sudden onset of symptoms. It has been suggested, on the other hand, that this form of meningeal disturbance may be due to a delay in the absorption of cerebrospinal fluid, and that there results a disproportion in the amount produced and in the amount absorbed, thus giving rise to an excess fluid in the ventricles and subarachnoid spaces. Changes of the nature referred to have not been verified by careful pathologic studies. In some cases serous meningitis undoubtedly represents an acute exacerbation of a previously existing or chronic hydrocephalus. It has been observed that serous meningitis may occur with remissions and exacerbations over a long period of years. In some of these cases a congenital hydrocephalus is present.

Trauma to the head may cause serous meningitis and in the mild cases the symptoms may not be recognized, whereas in some of the severe injuries a considerable time may elapse before the characteristic symptoms appear. Serous meningitis may be associated with nearly all the acute infectious diseases. It may occur during or after scarlet fever, measles, diphtheria, tonsillitis, mumps, influenza, pneumonia and whooping cough, as well as in the intestinal diseases of childhood. It occurs rarely before the first year of life and occurs most commonly between 1 and 5 years, though it has been recorded as late as the thirtieth year or even later.

Symptoms of serous meningitis may simulate those which occur in brain tumors without severe local manifestations or they may simulate meningitis, as they do in the patient referred to in the query. In the meningeal form the symptoms are rigidity of the neck, slow pulse, moderate fever (though it may be absent), nausea, vomiting, stupor, coma and delirium symptoms that occur in any form of meningitis. The pupils react sluggishly. They are often unequal. Most alarming of all the symptoms is the visual disturbance. Indeed, in some cases complete loss of vision may occur. The ophthalmoscopic examination may show choked disk similar to the condition found in brain tumor, or optic neuritis or optic atrophy may be observed. Paralysis of the cranial nerves is sometimes encountered, espe-

crilly of the abducens and the oculomotor nerves. Nystagmus, too, sometimes occurs. It has been suggested that this symptom is due to increased intracranial pressure caused by the hydrocephalic fluid, affecting the labyrinth. Sometimes the patients complain of partial deafness. In the severer cases resembling brain tumor the greatly increased intracranial pressure may bring about a fatal issue. If a spinal puncture is made, the fluid generally escapes under increased pressure and it is increased in quantity. It is clear and shows normal cell content and no organisms. The symptoms tend to recede after spinal puncture. There are a few cases in the literature in which herpes has been described in serous meningitis.

CHANGES IN NASAL MUCOUS MEMBRANE DURING MENSTRUATION

To the Editor—A woman aged 32, has a troublesome postnasal soreness either just before or just after each menstrual period. There is absolutely no nasal abnormality that can be demonstrated the nose never gives any trouble the patient rarely has a cold. This condition started some nine months ago and has become worse since tonsillectomy six months ago. She has moderately severe cramps and backache before menstruation begins, which are relieved when the flow starts. She has two children the youngest 7 years of age. She has a mild retroflexion but no cervicitis. The periods are regularly thirty-one days apart and last the normal time with normal character of flow. There is no history of syphilis and the Wassermann reaction is negative. The postnasal soreness never occurs during active menstruation. Just what connection is there between the postnasal area and the female generative organs? What would you suggest in the way of treatment? Please omit name.

M.D. Vienna.

M D, Virginia.

ANSWER—It has been known for a long time that during menstruation and pregnancy certain changes in the nasal mucous membrane may appear. Often it is merely a congestion of the mucosa, especially that covering the turbinates, particularly the inferior turbinates, and also the upper portion of the septum in the region of the so-called tuberculum septi. Furthermore, congestion of the pharynx and nasopharynx has been observed in some systemic conditions involving the general circulation. While the nasopharynx does not contain genital areas such as have been ascribed to the tuberculum septi and to the inferior turbinates, it is nevertheless possible that in some individuals these areas may be more sensitive at the time of menstrual periods. Some years ago, Eliess in his publications stated that the pains in the pelvis and lower portion of the back present at the time of menstruation could be relieved in many cases by application of a 5 per cent solution of cocaine in the upper portion of the septum and the inferior turbinate. It might not be amiss in this case to apply the solution carefully to the region of the posterior end of the nose and nasopharynx, to see whether any relief of symptoms can be obtained.

PAIN IN SHOULDER AND ARM AFTER REMOVAL OF BREAST CANCER

To the Editor—I have under my care a woman aged 74 who was operated on last June for cancer of the breast. I did not perform the operation. There was complete removal of the right breast and thorough cleaning out of the right axilla. Since her discharge from the hospital her case has fallen into my hands. The patient is suffering intense pain starting in the right shoulder and going down the arm into the fingers. There is also marked edema of the limb. The case is somewhat baffling and I am at a loss as to just what to do to reduce the swelling and relieve the pain, the latter seeming to be worse at night. By elevation of the arm I was able to reduce the swelling somewhat but because of the pain over the scar tissue due to the drawing I imagine, the patient is unable to maintain the elevation for any length of time. Can you advise me as to an efficient method of treatment for the pain and the reduction of the swelling? Kindly omit name and address

M D Michigan

MD Michigan

ANSWER—There are three possible causes for the pain from which the patient suffers (1) vertebral metastasis with pressure on the cord, (2) recurrent disease in the axilla with involvement of or pressure on the brachial plexus, and (3) lymphedema. Roentgen examination of the cervical and thoracic spine should help to establish or exclude the first possibility. Physical examination for recurrent nodules and the course of the disease may indicate recurrence. When these two possibilities are excluded there remains the condition of lymphedema. The exact causes of postoperative lymphedema not due to recurrent disease are not fully understood. It is suspected that a mild postoperative infection may be an important causative agent. The treatment has not been satisfactory. Elevation of the arm and gentle massage from the wrist toward the shoulder are of some help. In severe cases the Kondoleon operation has been resorted to, and some surgeons have reported successful results.

PSITTACOSIS

To the Editor—For the past two weeks and particularly the past week I have received numerous inquiries concerning the Pittsburgh psittacosis situation. I understand that one must have direct contact with the bird or person having the disease in order to contract it. Please advise whether I am correct in this assumption and if there is any possibility of any one contracting the disease by visiting or being employed in the stores that have had infected birds. M D Pittsburgh

ANSWER—In the majority of cases, psittacosis appears to have been transmitted from sick parrots. Occasional instances of apparent transmission from one person to another have been recorded. Knowledge of the exact mechanisms of transmission of psittacosis is imperfect and at the present time the possibility that one might contract the disease "by visiting or being employed in the stores that have had infected birds" cannot be denied.

PAIN AND NUMBNESS OF HAND AND FOREARM

To the Editor—A woman aged 50 suffers with pain or numbness in the right hand and forearm with stiffness and at times loss of touch sensation and slight edema. This condition started about seven years ago as a tingling in the hand and forearm as though it were asleep. It has grown progressively worse until there is now a great impairment to the usefulness of this member. She had an operation about five years ago at which time the left tube and ovary and the appendix were removed and also an amputation of the cervix and anterior and posterior colporrhaphy were done. Tonsillectomy and submucous resection were done fourteen years ago. The patient had typhoid twenty-three years ago. She has four children living and in good health. After the laparotomy she was relieved for about twelve months, which relief was probably obtained from not using the hand and arm. At present the discomfort is always present and is made worse by use. It seems to be worse during the night and keeps the patient from sleeping. She gets relief by applying cold to the extensor surface of her hand and over the area supplied by the median nerve. Heat aggravates the condition. She gets no relief from salicylates. She had an abscessed tooth removed two months ago but has seen no change in her condition. Roentgenograms of all the other teeth are negative with the exception of an impacted third canine tooth on the right side. This was found on routine roentgen examination and is causing no discomfort and is not abscessed (Her mother had a third canine.) General physical examination now is essentially negative. The blood picture is negative and the Wassermann reaction is negative. The blood pressure is 130 systolic 80 diastolic in both arms and the pulse is equal in the two wrists. There is no history of injury. Please omit name. M D, North Carolina

ANSWER—The question contains little information concerning the results of a neurologic examination. The only features mentioned are pain, numbness, occasional loss of touch sensibility, slight edema and stiffness. These suggest a possible irritation in the region of the brachial plexus or roots. Studies of the exact distribution of sensory and muscular disturbances might yield clues to a more exact localization of a lesion, and thus to a study of the region indicated for source of irritation, e.g., cervical rib or enlarged lymph nodes. A comparison of the sphygmographic curves and comparative studies of sweating on the two sides might yield suggestions of vascular or sympathetic changes, in connection with the latter it would be well to study carefully the reaction of the pupils.

THERAPEUTICS OF MALARIA

To the Editor—The following copies of prescriptions were given to a druggist to fill

Quin sulph	drs IISS	Sod bicarb	ozs III
Citric acid	ozs ISS	Sod citrate	ozs II
Mag sulph	ozs III	Calcium carb	drs I
Aquae q s	ad ozs VVI	Aquae q s	ozs VVIII
M		M	
S 2 tablespoonfuls t i d		S 2 tablespoonfuls 15 minutes	
Adrenalin 20 minims in water if vomiting		before other mixture	
		Atabrine tablets No 15	
		S One t i d p e	

At the time it was explained that the whole constituted a treatment for malaria as used by army doctors in some nearby camps of the Civilian Conservation Corps and that it was the accepted treatment as used in the army. Kindly comment in full on prescriptions and state the rationale for this treatment. Is it used as a standard treatment by the army medical corps men. Please omit name. M D Florida.

ANSWER—The same amount of quinine, 0.3 Gm three times a day, in the form of capsules or tablets will have just as good effect and save a lot of trouble, expense and unpleasantness to the patient. Any physician who prescribes quinine in this or other similar unpleasant solution should have to take a few doses of his own medicine. More than likely he would change his prescription.

Atabrine is a new but effective remedy for malaria. It relieves the clinical symptoms almost or quite as effectively and quickly as quinine. Many recent reports indicate that relapses are less frequent following a short period (one week) of treatment with atabrine than following a similar period with quinine.

The prescription for atabrine is entirely satisfactory. The combination of 0.3 Gm of quinine sulphate three times a day with the atabrine is better than either one alone.

SYPHILIS AND DIABETES

To the Editor—A white man married aged 52 had a course of antisyphilitic treatment six months ago. His syphilitic condition was picked up in the course of a routine examination. He had no recollection of a primary sore. Weekly urinalyses during the treatment were negative. At this time the second course of treatment was to be started as a routine. Urinalysis was done which showed 4 plus sugar. Blood sugar fasting was 274 mg. The Wassermann reaction was 2 plus. The twenty-four hour quantitative sugar was 20 Gm. The patient was placed on a diet antisyphilitic treatment was not started. One month later urinalysis showed sugar 4 plus. Blood sugar fasting was 178 mg. The quantitative twenty-four hour sugar was 15 Gm. Apparently a diet will not render the urine sugar free. Should I place him on a graduated diet and work out an insulin dosage to keep the urine sugar free? Then could his treatment be started while he is taking insulin or should antisyphilitic treatment be discontinued indefinitely? Searle's neoarsphenamine was used. Is there a possibility of the neoarsphenamine being an etiologic factor in the diabetes? What is the prognosis as to the progress of syphilis to advanced stages? Any suggestions will be appreciated. Kindly omit name. M D, Rhode Island

ANSWER—The case is evidently one of fairly mild diabetes, because the blood sugar tests are not particularly high. Evidence is lacking to show that the disease will not respond to diet, because values for carbohydrate, protein and fat are not recorded.

There is general agreement that diabetic patients today should take insulin unless they tolerate at least 100 Gm of carbohydrate and enough protein and fat to maintain a satisfactory body weight.

Antisyphilitic treatment could be started any time and begun quite independently of insulin or of diabetes. In fact there is a distinct possibility that the antisyphilitic treatment will help not only the syphilis but the diabetes as well. There is no probability of neoarsphenamine being an etiologic factor of the latter.

The prognosis of syphilis in a patient with diabetes is no different from that in one without diabetes.

THROMBOSIS AND SLOWING OF BLOOD STREAM AFTER THYROIDECTOMY

To the Editor—I would greatly appreciate any information you may be able to give me concerning the biochemical changes that may occur in the blood by the slowing of the stream following total ablation of the thyroid with their probable effects on thrombosis and pulmonary edema. My understanding of the events favoring thrombosis as obtained from the literature in these cases is as follows: Starlinger has shown that slowing of the blood stream favors agglutination of the platelets and a decrease in their electronegative charge. It favors a change in the albumin globulin ratio of the serum in favor of increased globulin which also causes a decrease in the electronegativity of the platelets favoring thrombosis. Also the change in the acid-base equilibrium increasing the carbon dioxide favors thrombosis by the lowering of the electronegative charge of the platelets and increases their number thus aiding in shifting the blood proteins to the globulin side. I should also like to know what biochemical effect if any slowing of the blood stream with its concomitant changes would have in favoring pulmonary edema. Please omit name and address. M D Massachusetts

ANSWER—The correspondent's understanding of the biochemical changes favoring thrombosis by a local or systemic slowing of the blood flow appears to be the last word in an extensive consideration of this subject. Observations favoring such a view are suggestive but ought to be substantiated by other investigators to a greater extent than they have been before the hypothesis can be registered as a fact. The incidence of thrombosis and emboli of the lung after thyroidectomy is less than after any other major operation. In Professor Quervain's clinic in Bern statistics show an incidence of fatal emboli of the lungs in 0.07 per cent of the cases as compared with 0.04 per cent in exploratory laparotomy and an average of 0.69 per cent in a total of 20,779 major operations.

Blumgart and his associates stated that the velocity of blood flow is directly determined by the metabolic demands of the body which is gaged by the basal metabolic rate. The main biochemical change after total ablation of the thyroid gland is reduction of the thyrotoxic substance, resulting in a marked drop in the basal metabolic rate. In many cases following thyroidectomy marked improvement in signs and symptoms of cardiovascular insufficiency with an increase in the vital capacity of the lungs may be noted. This occurs in spite of the fact that a definite decrease in the velocity of blood flow takes place. When edema of the lungs occurs in these cases it might be explained on the basis of complete exhaustion of the cardiac reserve.

Book Notices

Diets at Four Levels of Nutritive Content and Cost. By Hazel K. Stiebeling Senior Food Economist and Medora M Ward Assistant Economist Economics Division Bureau of Home Economics United States Department of Agriculture Circular No 296 Paper Price 5 cents Pp 59 with 9 illustrations Washington D C Supt of Doc Government Printing Office 1933

The circular presents for each of four planned diets—a restricted diet for emergency use, an adequate diet at minimum cost, an adequate diet at moderate cost, and a liberal diet—(1) the quantities of foods or food groups required (2) the nutritive value of the diet, and (3) the retail cost of the food supply as a whole. The data are presented in per capita figures as well as for individuals classified according to age, sex and activity, and for family groups. The prominence assigned to different kinds of food varies from diet to diet, because in comparison with their cost some foods and groups of foods yield better returns in nutritive values than others. Grain products, dried legumes and potatoes are given special prominence in the two diets of low cost. Other vegetables, fruits, lean meats, fish and eggs in the two diets of highest nutritive content and cost. Milk and other dairy products are emphasized in all diets and are given special prominence in the three adequate diets.

The nutritive values of the four diets are compared with one another and with tentative dietary standards. The restricted diet for emergency use provides approximately the minimal requirements of the body for the various nutrients and allows but little margin for safety. The minimal and moderate cost adequate diets provide enough of the different nutrients to cover average requirements for maintenance and growth and to furnish a fair margin of safety. The liberal diet is fully adequate. It includes items from different food groups in such quantities and proportions as to promote better than average nutrition.

Both the nutritive values and the costs of the four suggested diets may be modified by the selection made among individual articles of food within each food group. Costs are also greatly affected by the quality of the foods selected. Therefore a brief summary of quality and size grades for many foods has been included. Some of the other factors affecting costs are discussed briefly including the packaging of food, the size of

purchase, the seasonal variations in food prices, and local and general price levels. Many of these points are illustrated by tables and graphs.

The circular will be especially helpful for the planning of diets for institutions and public welfare relief. The literature cited is listed.

Case Studies in the Psychopathology of Crime. By Ben Karpman M.D. Psychotherapist St. Elizabeths Hospital Washington D. C. Volume 1. Cases I-V. Cloth. Price \$12. Pp 1042. Washington D. C. Mimeoform Press 1933.

The author, psychotherapist at St. Elizabeths Hospital, the United States hospital for the insane, at Washington D. C., and professor of psychiatry at the medical school of Howard University, is endeavoring to develop a better understanding of some of the problems of criminology, through intensive studies of criminals, seeking to discover particularly the psychogenic factors behind their criminal actions proper. The lives of only five persons, wards of the department of criminal insane at St. Elizabeths Hospital, fill this book of more than a thousand pages, each page $8\frac{1}{4}$ by $10\frac{1}{4}$ inches. A second volume is to be devoted to a discussion from a psychogenic standpoint of the data here recorded. These data include not only case histories such as are common to inmates of hospitals for the insane but in each case an autobiographic sketch by the inmate whose case history is recorded, the opinions that some of his fellow inmates have entertained concerning him, and intimate information as to his heredity, family environment, sex life, court records and other material gathered from all available sources. The distribution of the book is limited to persons having professional interests in its subject matter.

The prodigious and painstaking labor involved in the preparation of this volume are apparent in its size and detail. It is perhaps unfortunate that the data assembled concerning each person investigated are not arranged in chronological tables, so as to permit convenient study of his environment at each period of his life, and his reaction at that time. The present arrangement makes it difficult to detect and evaluate sequences of cause and effect and to distinguish them from merely chance sequences of time, so as to see better the evolution of criminality and insanity. Unfortunately, the study of the lives of any five insane criminals by any one person, however competent and well poised that person may be, can hardly be expected to yield results of the first importance. If the research on which the author has entered is to lead to such results, it seems desirable that his plan of investigation have the approval of other scientists working elsewhere in the field of criminology, with sane criminals as well as those that are insane, and that they participate actively in assembling case histories that are accurately comparable, and in synthesizing, analyzing and comparing all case histories assembled. Only in that way can the chances of error inherent in conclusions drawn from the study of as few as five persons, and the danger growing out of a possible unconscious bias on the part of a single investigator, be reduced to a minimum.

Diet and the Teeth. An Experimental Study. Part III. The Effect of Diet on Dental Structure and Disease in Man. By May Mellanby. Medical Research Council Special Report Series No 191. Paper. Price 5s. Pp 180 with illustrations. London. His Majesty's Stationery Office 1934.

This is the third of a series of reports on the subject of teeth with a view to determining whether dental disease, especially caries, is chiefly a problem of nutrition and if so whether this scourge can be prevented by a planned diet. The studies are a pioneer work marking a definite advance in knowledge of causes of dental decay and methods of prevention. The author concludes from her studies that liability of teeth to decay depends largely on perfection of structure, which in turn is to a great extent dependent on nutritional influences during growth, both prenatal and postnatal. Ill formed (hypoplastic) teeth are common and are particularly liable to invasion by bacteria. Tooth formation requires abundant supplies of calcium, phosphorus and vitamin D. These factors are necessary throughout life, especially for the natural processes of 'healing' of which teeth are capable and on which arrest of caries depends. The report gives evidence that two main conditions control the onset of caries: resistance due to structure and resistance due to constitution of the diet. The chemical agencies

of food leading to well calcified teeth are, at least in part, the same as those which increase or maintain the degree of immunity to caries in later life. Present knowledge of what foods produce well or badly calcified teeth can be applied to increase resistance of developed teeth and often arrest decay of diseased teeth. Major changes in the diet of pregnant and lactating women, of infants, and of children during the whole period of dental development and indeed during the whole life are recommended. The consumption of milk, eggs, cheese, animal and fish fats, and vegetables should be greatly increased and the consumption of cereals diminished and for children abolished. The novelty of the conclusions has subjected the work on which they are based to vigorous criticism and often disbelief. This report, as well as the preceding reports, is particularly important for stimulating further research into the possible nutritional causes of defective and diseased teeth and for modifying the diet of the public to take advantage of what has been learned for promoting better teeth.

The Carnegie Foundation for the Advancement of Teaching. Twenty Eighth Annual Report of the President and of the Treasurer. Paper. Pp 189. New York 1933.

This report will bring to many readers a heightened interest as well as profound regret because it represents the last professional activity of the late president of the foundation, Henry Suzzalo. He urges that among institutions of higher learning the spirit of rivalry give place to one of cooperation and that for the competitive individualism of the past there be substituted a consciousness of national responsibility. His plea for unrestricted educational opportunity for all through the lower collegiate division or junior college and a stringent limitation of attendance in the upper division or senior college will provoke more dissenting opinions than the suggestion that professional and graduate schools should be so limited.

In a chapter entitled "Is Education on the Right Track?" Dr. Pritchett, president emeritus of the foundation, declares that "the school has become a cramming place rather than an agency for training boys and girls to use their minds. In spite of fine buildings and an ever-growing list of studies, and of mounting cost, the typical child reads and speaks his native tongue badly. His handwriting is slipshod and formless. His command of elementary mathematical reasoning is weak. He has not learned to read books. In comparison with the training of the children in the elementary schools of France and Germany or of the board schools in England, he has learned none of these fundamentals thoroughly. Furthermore, in comparison with the foreign schools, both teachers and pupils are in a slavish dependence upon textbooks and on routine lessons out of textbooks. All these facts have long been admitted by those most concerned with education."

In another chapter Dr. Pritchett deplors the proposal to create a department of education with a secretary in the cabinet, and large appropriations under his control. "Such authority vested in the central government would be the most powerful machinery that could be devised for bending the beliefs and convictions of all communities to the purpose and will of a central autocratic power. Whenever such power to education has been entrusted to a central authority, local initiative and personal freedom have disappeared. Even religion, in a state-controlled system of education can be bent to the purposes of the state."

Formal education in our country in the last generation has gone through a period of inflation comparable to some of the processes of business inflation. Schools of every grade, from elementary school to the university, have sought to teach too many subjects in a superficial and demoralizing fashion. The typical graduate of our higher schools does not write or speak his own language correctly, nor reason through the simpler processes of arithmetic nor read good literature. What we need first of all in every state in the Union is a return to that ideal of teaching which shall make for simplicity, sincerity and thoroughness. The acquiring of a sound education lies in training the habits and powers of the mind. This is begun by learning a few subjects thoroughly, not by sampling many subjects. The attempt to equalize education throughout the Union would mean a continuation of the process of educational inflation in which the true aims of education are either

lost or obscured and all schools are forced to the uniform type of textbook education."

Other sections of the report deal with the system of teachers' retirement allowances, experiments in educational measurements in the state of Pennsylvania, a discussion on "The Learned Professions and Their Organization," and the routine reports of the officers of the foundation.

Lessons on the Surgical Diseases of Childhood. By William Rankin M.B. Ch.B. Paper Price, 21/- 1 p 190 with illustrations. Glasgow: Alex. MacDougall 1934.

This represents a collection of twenty lectures and demonstrations given to students of the Glasgow University on the subject of surgical diseases of children; it does not pretend to cover the subject thoroughly but to lay a foundation for a further study and to familiarize the student with the most common surgical conditions in childhood. It contains chapters on harelip, cleft palate, nevus, torticollis, tonsils, spina bifida, common chest and abdominal lesions, genitourinary conditions, surgical tuberculosis, fractures and anesthesia. The weak spot of the presentation of the subject lies in the fact that the lessons are based on the older surgery exclusively, ignoring completely new methods of approach, such as treatment of hemangiomas with radium or carbon dioxide snow, few will agree with the author claiming that in such conditions a fine household needle heated in an alcohol lamp is not equaled by any more expensive apparatus for this purpose. Recommendation to use a rigid right angled Herth's tonsillotomy and chloroform for removal of the tonsils will hardly meet with the approval of American surgeons. Certain abbreviations, such as P. S. T. or G. P. T. dressings, are not familiar to an American reader. Advocating rib resection in every case of empyema in children seems to be, to say the least, too radical. Several sketches are rather primitive, while some of the numerous beautiful reproductions of photographs lack explanatory notes. An uncritical description of a wide array of methods may be confusing and bewildering to a novice, but a one-sided presentation based on ultraconservatism certainly is misleading and not sufficiently instructive. The book may supplement lectures on surgical diseases in children and merely in this capacity it may be recommended to students.

Wilhelm Conrad Röntgen and the Early History of the Roentgen Rays. By Otto Glasser. Director Radiation Research Department Cleveland Clinic. With a chapter Personal Reminiscences of W. C. Röntgen. By Margaret Boveri. Cloth Price \$6. Pp 494 with 96 illustrations. Springfield Ill. & Baltimore Md. Charles C. Thomas, 1934.

If ever there was an epoch-making discovery in medicine, it was the development of the X-rays, primarily through the fundamental discoveries of Roentgen. In this book Dr. Glasser traces that discovery from the fundamental investigations made by earlier investigators to the present status of roentgenology as a science. When the German edition first appeared, it was recognized as a significant contribution to medical biography. Not only is the book well written but it is authentic. It is presented in the English edition on a fine stock. The book is full of handsome original illustrations, well reproduced, and is supplemented by an excellent bibliography and an index. The numerous anecdotes and quotations from correspondence and original writings in the chapter of personal reminiscences of Roentgen by Margaret Boveri make this contribution an intensely human document.

The Teaching of Preventive Medicine in Europe. By Carl Prausnitz M.D. M.R.C.S., L.R.C.P. Professor of Hygiene in the University of Breslau. University of London Health Clark Lectures 1932 delivered at the London School of Hygiene and Tropical Medicine. Cloth Price \$3.75. Pp 186 with 37 illustrations. New York & London: Oxford University Press 1933.

The University of London, in arranging these lectures, determined that their general scope should be "the educational, cultural and humanistic aspects of preventive medicine, as distinct from the technical and manipulative training essential to its practice and progress." The objective pointed out by Sir George Newman "is a wider outlook on the physical art of living, the advance of personal hygiene, and the origin and development of preventive medicine, together with its sanitary and social evolution, both in temperate climates and in the tropics." The organization and discipline of the various types

of workers engaged in public health in a number of European countries are described. France, Spain and Greece are but lightly touched on. Italy is not mentioned. Germany and England come in for a comprehensive analysis. The most interesting part of the book, however, is that which deals with the more recently undertaken activities of Poland, Hungary, Czechoslovakia and Yugoslavia. These countries, recognizing the nation's health as a major objective, have been able largely to consolidate all the agencies directed to this end and so avoid the complexity and inefficiency that inhere in many of the older systems of administration. In Russia, efforts to establish a national health service are of course vigorous and unconventional. The results cannot yet be appraised. For the student of public health administration, the book contains much that is of interest.

Recent Advances in Endocrinology. By A. T. Cameron M.A. D.Sc. F.R.C. Professor of Biochemistry Faculty of Medicine University of Manitoba. Cloth Price \$3.50. Pp 365 with 54 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc. 1934.

This addition to the valuable "recent advances" series represents a serious attempt to prepare in brief form a critical summary of the newer concepts of glandular physiology. The author has included a tremendous amount of information previously unavailable within the compass of a single book. While some of the sections appear to be excellent, the work as a whole is characterized by uneven treatment in selection and in critical analysis of the material.

The author proposes the following statement as a fundamental concept: "In the different pathological states of a gland it may produce too much or too little of [the] specific compounds, but it does not produce abnormal compounds." Considering the present precarious state of our knowledge of the chemical constitution of glandular secretions, such a claim is premature. Its value even as a working hypothesis must be questioned, it may lead readily to unfortunate conclusions. Cameron's remarks on the deplorable state of endocrinologic nomenclature are pertinent, yet it cannot be said that the names used by him (such as "adrenine," "pituitrin") are in all cases well chosen. His objection to the widespread misuse of the word "hormone" is commendable, but a more strict delimitation of its employment or even its abolition would be desirable.

The priority of Hanson in making a potent extract of the parathyroid glands is admitted with apparent reluctance, but credit for establishing the presence of an active principle is given to Collip. The author quotes the work of Bazett, who claimed that suprarenalectomy in cats resulted in a fall of blood pressure with death six hours later. Rogoff has demonstrated that cats suprarenalectomized with adequate surgical technique live for several weeks. Bazett's animals must therefore have been in surgical shock, in which condition blood pressure determinations would be of no value whatever in proving the thesis of epinephrine deficiency.

For conservative claims in original papers, the author appears to penalize some investigators by discounting their statements in large part or completely, while extravagant claims made by others receive his full credence. In reporting the recent work on the suprarenal cortex, for instance, he states that the extract of Rogoff and Stewart has produced "slight, but only very slight, improvement." Reference to the original paper indicates that the results obtained, far from being "very slight," were quite promising. Subsequent papers by Rogoff giving further data on the preparation and the clinical use of his extract are omitted altogether. Yet the astonishing claims of Hartman and of Swingle and Pfaffner are reported voluminously. Their methods of making allegedly highly potent extracts are described, that of Swingle and Pfaffner in meticulous detail. No mention is made of the work of Eagle, who has shown that extracts made by the Swingle-Pfaffner method are contaminated with significant amounts of choline, thus rendering worthless many of the investigations conducted with these preparations. The use of a solution containing choline in the treatment of Addison's disease must be viewed with alarm by any one acquainted with the pharmacologic potentialities of this amine. Nor does the writer include a description of Rogoff's fundamental contribution in the experimental production of the Addison syndrome in animals.

The sections devoted to the pituitary principles and to the ovarian and placental factors leave much to be desired, even in view of the limitations of space imposed in a volume of this sort. The material on clinical application of these preparations is incomplete, uncritical and, although tending toward the conservative, still unpardonably optimistic.

Space forbids a more detailed discussion of the many other serious lapses in choice of source material and in critical judgment that occur throughout the book. Despite its wealth of information, this work adds further evidence to the thesis that the field of "endocrinology" is already too vast to be adequately treated in its entirety by any single investigator. By popularizing misconceptions, the author's efforts may do more harm than good.

Treatment of the Commoner Diseases Met With by the General Practitioner By Jewellys F. Barker M.D. Visiting Physician Johns Hopkins Hospital Baltimore. Cloth Price \$3. Pp. 319. Philadelphia & London J. B. Lippincott Company 1934.

The desirability of brief synopses of achievements in the special fields of medicine has been a long felt want by those engaged in general practice. This has been supplied in some measure by reviews, digests and abstracts in current medical journals. However, such a book as this will be welcomed by many physicians. The author is well equipped by virtue of his training and experience to anticipate the practical needs of those for whom he is writing. In these ten chapters only the most recent facts concerning the management of the common disorders are considered. They concern both factual data and point of view. For example, the author devotes the opening chapter to advances in the methods of studying patients and practicing medicine and in the following chapter considers some of the recent trends in infection and resistance. All the discussions are concise and practical. The writer makes no pretense at completeness or systematic organization. The text is decidedly an informal presentation, touching briefly on the recent trends in management of disorders in which the general practitioner might be interested. The bibliographic references are numerous and recent and serve a most useful purpose to those who wish to go beyond the confines of this book. The work is essentially an answer to the anticipated desire of the man engaged in the general practice for recent thought on the common diseases. It should be well received by those for whom it is intended.

If I Have Children By G. Francis Smith M.R.C.S. L.R.C.P. Cloth Price \$1.75. Pp. 133. New York & London Oxford University Press 1933.

The author of this concise treatise is a physician projecting himself in three dimensions in the roles of child father of a family and medical practitioner. He has fused the problems of these three roles so that the reader has a common sense perspective of fatherhood and motherhood. The book is refreshing in its sincerity and marred only slightly by the concluding last chapter on some prosaic aphorisms. The scope of the book includes the selection of the parents, the prenatal stage and the development of the child. Problems of childhood are adequately touched on for a book of this type and the author treats them with balanced sympathetic understanding. While the text is general, it is stimulating and worth reading.

A System of Clinical Medicine Dealing with the Diagnosis, Prognosis and Treatment of Disease for Students and Practitioners By Thomas Dixon Savill M.D. Edited by Agnes Savill M.D. Assisted by E. C. Warner M.D. Ninth edition. Cloth Price \$9. Pp. 1063 with 169 illustrations. Baltimore William Wood & Company 1933.

Since the first edition of this book appeared in 1905 there has been little alteration in the plan of presentation. This differs from most textbooks of general medicine in that it attempts to follow the mental steps taken in the gradual process of forming a diagnosis. Thus, the first chapter gives a general scheme for examination of a patient and deals with the general principles underlying methods of observation, diagnosis, prognosis and treatment. The succeeding chapters deal with symptoms and signs referable to several organs or anatomic regions of the body and the disease that may cause those symptoms. Much credit is due Dr. Agnes Savill for her splendid work in perpetuating the ideals of her husband without undue expansion

of the book. So many advances have taken place since the original plan of the book was formulated that careful editing was necessary to keep this from becoming an unwieldy volume. This has been accomplished in some measure by substituting tables for long discussions. While many phases of the book have undergone revision, the chapters on nervous diseases and diseases of the heart are the most noteworthy in this respect. Other chapters could have profitably been subject to the same degree of revision as they suffer by comparison in their present form. This work is not intended to serve the purpose of a reference book or comprehensive textbook of general medicine. Its greatest field of usefulness will be found by medical students and those starting the practice of medicine who can possess this book in addition to other textbooks of medicine that cover the various subjects in a more exhaustive manner. This volume serves a most useful purpose if it does nothing more than help the reader to systematize his knowledge for the purpose of applying it at the bedside.

Birth Control in Practice. Analysis of Ten Thousand Case Histories of the Birth Control Clinical Research Bureau. Text and Tables. By Marie E. Koop Ph.D. Prepared under the supervision of a Scientific Advisory Committee. With a foreword by Adolf Meyer M.D. Cloth Price \$3.75. Pp. 290. New York Robert M. McBride & Company 1934.

This as a record of 10,000 cases from the Margaret Sanger Birth Control Clinics. It supplies a great deal of information about those clinics but cannot be said to constitute a scientific document. The evidence would seem to indicate that all the common methods are successful if used correctly and that those methods which place the smallest burden on the intelligence of the user are likely to be most successful. There is a great deal of tabular matter providing the data of the clinics studied. It seems likely that the social data provided are of greater significance than the medical data.

Basic Science Acts Exemption from Examination, Constitutionality—Shenk, a naturopath, applied to the Minnesota State Board of Examiners in the Basic Sciences for a certificate of registration, to be issued without examination, under the provision of the basic science act that exempts from examination every one who on the day the act took effect was lawfully authorized to practice the healing art and regularly licensed or registered in the manner then required by law. His application was rejected. He petitioned the district court, Hennepin County, for a writ compelling the board to issue the desired certificate. When the court rejected his petition, he appealed to the Supreme Court of Minnesota.

Shenk claimed that although he was not licensed or registered when the basic science act became a law he was at that time lawfully authorized to practice the healing art. He argued that the practice of drugless healing, of which naturopathy was a part, was not forbidden by the Minnesota medical practice act, that neither a license nor registration was then necessary to authorize the practice of naturopathy and that no law made it even possible to obtain a license or to register for the purpose of so practicing. Shenk contended that so much of the basic science act as purported to make licensing or registration a condition precedent to exemption from examination required of him an impossibility and should be regarded therefore as surplusage and void.

The Supreme Court held however, that Shenk, as a naturopath was unlawfully engaged in the practice of medicine within the meaning of the medical practice act when the basic science act took effect and that he was not entitled to the benefit of the provisions of the basic science act authorizing registration without examination. The practice of medicine said the court as defined by the medical practice act includes every one who shall for a fee prescribe direct or recommend for the use of any person any drug or medicine or other agency for the treatment or relief of any wound fracture or bodily injury, infirmity or disease. Naturopaths use herbs and other so-called natural methods for the alleviation of the ills of the human

body Naturopathic methods are, in any event, within the legislative inclusion of "other agency for the treatment or relief of any bodily injury, infirmity or disease." The Minnesota statute defining the practice of medicine was not enacted for the benefit of my profession or school or theory of medicine. Certain schools of healing are excepted by statutes from the category of the practice of medicine, which, but for the exempting statutes, would be within that category. The chiropractic practice act and the osteopathic practice act each declares expressly that its licentiates are not engaged in the practice of medicine or surgery. Naturopaths, however, have not yet been placed in a separate statutory classification. The statutory definition of the practice of medicine contained in the medical practice act is broad enough to include the activities of a naturopath.

Shenk claimed further that the basic science act bridged his privileges and denied him due process and equal protection of the law and that it was therefore unconstitutional. This claim, said the Supreme Court, is without merit. The act does not ban naturopathy, it regulates it. The basic science statute is the latest addition to regulatory legislation of this character. It departs somewhat from the older definition of the practice of medicine but of the newer and broader category of the practice of healing defined by the act naturopaths have no just complaint on constitutional grounds. Nothing has been brought to our attention said the court, to enable us to override the legislative judgment either as to the reasonableness of its regulation or the classification of the basic sciences. The practice of healing, as much as the practice of medicine if not more—postulating the existence of some real difference between them—imparts no right that is not subordinate to the police power of the states. In *State v. Brodus*, 181 Minn. 341, 232 N. W. 517, said the Supreme Court we sustained the basic science act against the objections then made based on its exclusions. What was then said is enough to dispose of the present objections to its inclusions.

The order of the court below sustaining the objection to Shenk's application for a certificate of registration in the basic sciences to be issued without examination, was affirmed—*State ex rel. Shenk v. State Board of Examiners in the Basic Sciences* (Minn.) 247 N. W. 392, *Rehearing* 250 N. W. 353.

Workmen's Compensation Acts Admissibility of Statements by Employee to Attending Physician—On April 26, 1929, a physician found that Helminsky's right testicle was swollen and that he had fever when he returned home from his day's work. Thereafter he was "not very well," but he worked from time to time. Later it was found that he had "tuberculosis of the chest" and he was sent to a hospital. He died, Nov. 3, 1929. Death was attributed to tuberculosis of the testicle, which was disclosed by autopsy. His widow, attributing his death to an accidental injury arising out of and in the course of his employment, instituted proceedings for compensation under the workmen's compensation act of New Jersey. A judgment of the court of common pleas, affirming an award in her favor by the workmen's compensation bureau, was reversed by the supreme court, and she then appealed to the Court of Errors and Appeals.

To substantiate her claim, the widow relied mainly on the testimony of the attending physician that the deceased employee had said that he fell against a wheel while he was at work. This testimony, said the Court of Errors and Appeals, was clearly inadmissible. The general rule in New Jersey is that statements made by an injured person to his physician for the purpose of treatment and diagnosis such as statements relating to symptoms and feelings, are admissible in evidence. But statements made to an attending physician as to the cause of an injury or as to the place where it occurred are inadmissible. The workmen's compensation bureau is not bound by technical rules of evidence, but it must ascertain the parties' substantial rights from competent evidence. Hearsay testimony may be received by the bureau without necessarily resulting in reversal but such hearsay testimony cannot form the basis of an award of compensation. Since there was no competent evidence that the employee's death in this case was due to an accident, the judgment of the supreme court disallowing compensation was affirmed—*Helminsky v. Ford Motor Co.* (N. J.) 168 A. 420.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Unusual Sinus Tachycardia—Field and his associates present a case in which there was a remarkably rapid sinus tachycardia—200 per minute and more. The extreme tachycardia, thought at first to be paroxysmal auricular tachycardia, persisted for four weeks and led to advanced congestive cardiac failure in an otherwise healthy man 40 years of age. After the usual methods of interrupting an attack of paroxysmal tachycardia had failed, an attempt was made to terminate the rapid heart action by exposing the vagus nerves in the neck and stimulating them electrically. There was however no demonstrable effect on the heart. Subsequently, partial heart block due to digitalis, resulted in slowing of the ventricles and was followed by improvement. Eventually the auricles gradually slowed the heart block disappeared the cardiac response to vagal activity returned and the patient recovered. This course of events strongly suggests that the tachycardia was in reality an extreme sinus tachycardia due to failure of vagus inhibition.

Electrocardiogram Produced by Experimental Rupture of Auricle—Randles and his associates describe experiments that show that alterations in the RST component of the electrocardiogram simulating those associated with coronary occlusion may be produced by experimental auricular rupture with resulting hemopericardium. These electrocardiographic changes have not been found immediately after producing a hemopericardium but only following an interval of several hours. The changes have been observed to persist for some time after the absorption or withdrawal of the fluid from the pericardial sac. The variations in the RST component were not due to the auricular injury but were associated with considerable amounts of fluid in the pericardial cavity. The authors cannot give a complete explanation of the mechanism of the production of the electrocardiographic changes in their experiments although the development of thrombema as previously discussed may well be a most important factor. Another method of producing RST changes in the electrocardiogram has been reported which

adds to the existing evidence that the so called coronary T wave is not pathognomonic of coronary occlusion.

Jugular Pulse in Diagnosis of Ventricular Tachycardia—Prinzmetal and Kellogg state that paroxysmal ventricular tachycardia may often be differentiated clinically from auricular tachycardia when jugular pulsations at a slower rate than the apical rate are present. They report a case in which a diagnosis of paroxysmal ventricular tachycardia could not be definitely made from the electrocardiogram but in which the diagnosis was made by the presence of jugular pulsations. It is suggested that there may be many similar cases in which this clinical sign alone could make a positive diagnosis or in which it would be a necessary supplement to the electrocardiogram in diagnosis. During ventricular tachycardia the most common auricular rhythms in the order of frequency are an independent rhythm, auricular fibrillation and retrograde rhythm with partial block. The authors conclude that the sign has limitations but is applicable to about two thirds of the reported cases. The coexistence of auricular fibrillation is the only important condition that renders the sign valueless.

Tumors of Suprarenals—Burke's survey of 371 cases coming to necropsy shows that the suprarenal is a site of metastatic involvement in a relatively high proportion of malignant tumors. The majority of malignant tumors will metastasize to the suprarenal and his series shows primary lesions in various locations in the body. Certain types of tumor however metastasize more readily to the suprarenal than do others. Either suprarenal may be involved depending on the location of the original lesion. The suprarenal shows metastases in many cases in which there is no general dissemination. The medulla is more frequently the site of metastatic neoplasm than the cortex.

Simultaneous Occurrence of Malignant Disorders and Tuberculosis—In a review of more than 15,000 cases at the clinic for the diagnosis and treatment of tumors Thibaudau found only twenty-two cases in which there was definite association of cancer and tuberculosis. Diagnosis of the tuberculous process was made roentgenologically or by positive finding of the tubercle bacillus in the sputum or section while the malignant condition was established in each case by histo-

logic examination. It seems probable that many actual cases of tuberculosis have not been recognized, owing to the difficulty of interpretation of roentgenograms when a malignant process is coexistent or to the difficulty of securing proper material for laboratory examination. The author concludes that the coexistence of an active malignant growth and tuberculosis in the same patient is uncommon. On the other hand the fact that the two conditions are found at times in the same patient and often closely associated in the same organ, would seem to argue against an antagonism between them. It may even be plausible to suppose that the chronic irritation produced by a tuberculous lesion might be the exciting cause in the production of a malignant neoplasm.

her associates tried to test the efficacy of hypertonic solutions of dextrose in stimulating diuresis using solutions from 23 per cent in an effort to find an optimal concentration of dextrose content of the blood and that of the urine were determined in fifteen infants presenting severe gastro intestinal ation with diarrhea dehydration and acidosis after the m to see if there was any relation between diuresis and glycemia or between diuresis and glycosuria. The principal acid and base constituents of the blood were determined before and after treatment to supplement a clinical evaluation of the efficacy of the therapy. The authors observed that the stage of gastro intestinal intoxication is largely responsible for the accompanying acidosis since it leads to a retention of acid ions in the body. The primary aim of the initial treatment should therefore be the restoration of an adequate flow of urine. Hypertonic solutions of dextrose administered intravenously serve this purpose. When combined with hypodermoclyses of saline solution they furnish fluid and electrolytes and stimulate renal function. Improvement in the clinical condition and acid-base status of the blood has resulted from this treatment.

Transverse Bands in Bones of Tuberculous Child—

Miller and Rubell state that, according to the literature disturbances in the growth of the bones such as they describe in their case may be caused by deficiency diseases (rickets, scurvy or any chronic debilitating condition). From a study of the case it would be fair to assume that the hindrance to the growth of the bones took place between the age of 2 and 3 years, because only three centers of ossification are seen in the wrist and foot which exhibit the curved bands corresponding to the transverse bands in the long bones and because the centers that ossified at a later date do not reveal these transverse bands. From the history and physical examination there is no evidence that the patient ever suffered from rickets or scurvy. No phosphorus was ever administered to the child may have been given. As the patient now suffers from a proved active tuberculosis of the hip joint the authors are tempted to assume that the tuberculous infection may have been present in a latent form since early childhood and that it constituted

the etiologic factor. They hesitate to consider this case as offering definite proof of a correlation of tuberculosis with the formation of these transverse bands. They feel, however, that in this case, in which no evidence exists other than the known tuberculosis of the hip joint, there may be a definite relationship between the two.

Birth Injury of the Occipital Bone—Hemsath reports

thirty-two cases of separation of the posterior intra occipital synchondrosis and calls attention to the fragility of the base of the skull in the full term fetus. The synchondrosis between the squamous and lateral portion of the occipital bone, because of its weakness and close proximity to the medulla oblongata, makes the base of the fetal skull susceptible of grave traumatic injury during delivery. This injury consists of a separation which may be called an osteodiasis since the term fracture is inapplicable. The thirty-two cases of osteodiasis occur in 166 consecutive necropsies performed by the author on viable fresh stillbirths and neonatal deaths during a period of two years. The necropsy rate was 71 per cent of the necropsies on viable delivered by version and breech extraction in 33 per cent each of forceps deliveries and of primary breech extractions and in 23 per cent of spontaneous deliveries. Of the injuries 72 per cent showed the squama depressed beneath and overriding the lateral portion and 38 per cent showed gross traumatic injury of the cerebellum. In forty-eight consecutive necropsies delivered by version and extraction and by primary breech extraction occipital osteodiasis occurred in 42 per cent a

frequency equal to that of subdural cerebral hemorrhage and of tentorial laceration and twice that of fracture of the vertebra. In forceps deliveries this occipital injury was found in one third of the thirty cases examined post mortem. Its occurrence in low forceps delivery was rare. The injury was found twice in spontaneous vertex deliveries when extreme difficulty was encountered in the delivery of the shoulders. In preventing occipital osteodystasia in forceps deliveries, careful cephalic application should be made and the line of traction should not force the occiput directly against the symphysis. In delivery of the after-coming head the occiput should be protected at the symphysis by attention to the direction and force of traction. Manual traction on the head for the delivery of shoulders should be applied to the sides of the head, the occiput being avoided.

Calcium in Treatment of Dysmenorrhea—Boynton and Hartley state that, of forty-nine cases of essential dysmenorrhea treated with calcium or with calcium and viosterol thirty-three were greatly benefited and sixteen seemed to receive no relief. The symptom of bruising easily seems to indicate, in cases of essential dysmenorrhea, that a more favorable response to calcium therapy may be expected than in cases not showing this symptom. The calcium was administered in the form of calcium gluconate by mouth. It was given daily in doses of 60 grains (3.9 Gm) for from ten to fourteen days before the onset of the menstrual period and continued through the first two days of the period. When viosterol was given with the calcium gluconate the dosage was 30 drops daily during the same period. An alkaline mixture, which was used alone in a few cases and with calcium gluconate in other cases, consisted of equal parts of magnesium carbonate and sodium bicarbonate. The dosage used was 60 grains three times a day for ten days before the onset of menstruation. What the effect of magnesium carbonate in preventing dysmenorrhea may be is unknown. Carswell and Winter have shown that with adequate phosphorus intake magnesium appears to favor calcium storage instead of causing calcium loss. There seems to be little therapeutic difference with variations of the drugs. In the cases reported, the drug was taken before two or more menstrual periods.

Missed Abortion with Superimposed Pregnancy—Forster observed a case of missed abortion in which a second pregnancy supervened within a month and went on to term. The patient continued to carry both a living and a dead fetus for nine months, until delivered by cesarean section the dead fetus having been carried for fourteen months, five months as a living fetus and nine months as a dead one. The second or superimposed pregnancy pursued a normal gestation of nine months. Convalescence was uneventful and a rapid recovery was made. The child is well and has developed normally. The mother has since had her gallbladder removed for cholelithiasis and has just recently delivered spontaneously a living female child, following a normal gestation.

New Method of Reading Friedman Test—In performing the Friedman modification of the Aschheim-Zondek test by the routine technic, Davis and his associates recorded the pupillary reaction of the rabbit immediately after injecting the urine into the marginal ear vein and then checked the result by the accustomed operation on the animal. A positive report was correct in 134 of 148 reports (90.6 per cent) and a negative report was correct in seventy-seven of ninety-four reports (81.8 per cent). The pupil of the rabbit reacts in a variety of ways. It will frequently contract to a size of about 2 mm while the urine is still being injected. In most cases however the pupils in the positive cases will react in from one to five minutes the contraction lasting from one to ten minutes. The dilatation of the pupil occurs in the same manner. In reading the test the authors read as positives only those cases which showed a decided contraction of the pupil paying no attention to dilatation of the pupil. Among the last 125 cases there have been fifteen in which a dilatation of the pupil occurred and the test was positive on operation on the animal. This error undoubtedly accounts for a few of the false negative reports. With reference to the false positive reports, they have no explanation at the present time except that eight of them occurred at about the same time on one group of eight rabbits that came into the laboratory together.

Silicosis and Its Relation to Tuberculosis—Gardner points out that at least 75 per cent of human beings who develop silicosis die of tuberculosis, which may make its appearance at any stage of the disease. The infection may already exist in a latent form when the individual takes up his occupation in the dusty industry, or it may be acquired subsequently. In some instances it may not become manifest until years after the exposure to dust has ceased. Animal experiments have demonstrated that partially healed primary foci of tuberculosis may be reactivated and rendered progressive by inhalation of silica. Serial roentgenograms of human beings exposed to silica have demonstrated reactivation of latent apical tuberculosis in the same manner. It seems probable that if lesions contain living tubercle bacilli, the dust will ultimately cause the lesions to become progressive. In the silicotic experimental animal, subsequent infection with attenuated tubercle bacilli tends to produce a rapid type of disease, which terminates fatally within three or four months. The nonsilicotic controls practically never die of such infections. When the practice of employing in silica industries only men whose chest roentgenograms are normal has been in force for some years the relationship between silicosis and the complicating infection should become more clearly defined. In the roentgenogram of silicosis complicated by early tuberculosis the alteration in the character of the nodules is manifested by a peculiar fluffiness and haziness or their outlines. Furthermore at some point in the lung the characteristic uniformity of distribution is interrupted and there is a marked tendency to aggregation of the nodules. When the process is far advanced the localized massive leathery fibrosis casts dense shadows with ill defined radiating borders. Often such changes are symmetrically located in the subclavicular or middle portions of both lungs. The combination of silicosis and tuberculosis is a new condition and not merely a combination or a superimposition of one process on the other. The combined disease sometimes progresses rapidly and terminates fatally within a few months at other times it is chronic.

length, lead increased in the excreta during acidosis and diminished greatly under calcium therapy. The value of calcium therapy was shown in the patient with neuromyelitis optica. Calcium stopped the advancing myelitis and caused lead to disappear from the spinal fluid. It is too early for the authors to state whether or not calcium is a satisfactory therapeutic agent in multiple sclerosis. They cannot state dogmatically that because lead is found in the central nervous system in the spinal fluid in the bones and liver and in the excreta it is therefore the cause of the disease. The constant association, however, of lead in every case of multiple sclerosis of the type under discussion that they have studied builds a rather strong meriting argument, provided they have not overlooked some fault in methods and have not interpreted their observations wrongly. More evidence may be brought to bear on the subject by experimental work now under way by further study of cases and by investigations in other clinics. They believe that their work to date suggests lead as the possible etiologic agent in multiple sclerosis of the exacerbating and remitting type.

Alcoholic Myelopathy Associated with Alcoholic Encephalopathy—In a previous report by Schilder and Bender (the author) a series of five cases of alcoholic encephalopathy (hemorrhagic poliencephalitis superior of Wernicke) were reported, and several different clinical groups were discussed and correlated with the neuropathologic changes in the brain stem and cortex. The author discusses clinically five more cases of alcoholic encephalopathy and gives the histopathologic changes of the brain stem and cortex as before. In addition, studies of the spinal cord were made. In every case of alcoholic encephalopathy in which the spinal cord was studied a myelopathy was found that appeared to be an extension of the same type of lesion that was found in the upper brain stem and dependent in its distribution on the same factors, namely the proximity to the spinal fluid about the spinal cord and the distribution of the vascular supply to the spinal cord. The lesion also shows a specific electivity for the vegetative centers being most severe in and about the lateral horns and Clarke's nuclei and the posterior horns of the thoracic level but also involving other parts of the cord especially the dorsal columns and the periphery of these columns. Schilder and the author showed the correlation between the clinical features in the psychic, motor and vegetative fields of the various clinical groups of alcoholic encephalopathy and the pathologic changes in the cerebral and cerebellar cortices and in the brain stem. The author now shows a comparable correlation between the motor, sensory and vegetative disturbances and the lesions in the spinal cords in all cases of alcoholic encephalopathy in which the spinal cord has been examined.

Procaine Hydrochloride and Nupercaine in Intradural Block Anesthesia—Holder uses a combination of nupercaine and procaine hydrochloride in block anesthesia so as to derive the advantages of both and perhaps do away with their disadvantages. In a patient properly prepared for spinal anesthesia i.e. with the administration of 50 mg of ephedrine in lower abdominal cases and 100 mg in upper abdominal cases fifteen minutes before lumbar puncture the lumbar tap is made with a fine gauge needle in the second or third lumbar space

as outlined by Huff, then 50 mg of procaine hydrochloride crystals is dissolved in 2 cc of a 1:200 solution of nupercaine. Of the seventy-four cases forty-four showed an average fall of systolic blood pressure of 20.4 mm of mercury, fourteen were stabilized without fall or elevation, and sixteen showed an average elevation of blood pressure from the preanesthetic level of 23.6 mm of mercury.

Recovery of Gonadotropic Substances from Urine of Pregnant Women—Davy proposes a method for preparing extracts of gonadotropic substances from urine of pregnant women which involves shaking acidified urine with Lloyd's reagent elution of the dried residue with 50 per cent aqueous pyridine, precipitation of the active material by acetone at 95 per cent and suspension of the active solids in water for injection. Extracts prepared by this method have been assayed with controls of whole urine. Approximately duplicate ovarian effects are secured with equivalent doses. The injection of the equivalent of 1,000 cc of urine gave no toxic effects. The extracts are apparently free from follicular hormone, since they have no effect on the uteri of immature castrated female rats. In eliminating variation in the response to gonadotropic substances rats weighing from 35 to 45 Gm 24 days of age are injected once daily for five days. At necropsy on the sixth day the ovaries are examined for increases of 100 per cent in weight and for corpora lutea. The titration of minimal effective doses with a small number of test animals is facilitated by this scheme. The author states that incomplete recoveries of gonadotropic substance are due to losses rather than to inactivation. Decreased potency after low temperature evaporation is due chiefly to retention of active material on urinary solids. Acetone precipitations are incomplete unless the final concentration is from 94 to 95 per cent.

Treatment of Sexual Underdevelopment—Sexton treated thirteen boys presenting genital underdevelopment and ranging in age from 10 to 21 years with intramuscular injections of the anterior pituitary like hormone of pregnancy urine. Eleven of the subjects responded to treatment by an increase in the size of the external genitalia and the appearance of secondary sex characteristics. These eleven were obese while the two who failed to respond were thin. The treatment instituted in these two cases was limited. Cryptorchism was present in six of the thirteen patients and in four of these six the

testicles localized in the scrotum after treatment. In one, a boy 18 years of age, the right testicle was the size of a grapefruit seed localized high in the inguinal canal, while the left testicle was undefined. After daily injections of 300 units over a period of four months, both testicles were well defined in the scrotum. After continued daily injections for another four months, the testicles developed to the size of hazelnuts and a sprinkling of pubic hair appeared for the first time. Another boy with testicles in the canals that were differentiated only by local thickening was 15 years 9 months old when injections of 300 units, five days a week, were begun. After six months the testicles had increased to the size of hickory nuts and lay just out of the scrotum. Pubic and axillary hair, not present before, had appeared. The dosage and duration of treatment were dependent on the degree of underdevelopment and the age, those in early adolescence responding most favorably.

Effect of Pregnancy Urine Extract on Hyperthyroidism.—The studies of Starr and Patton show that three patients of menopausal age and a boy of 17 years suffering from hyperthyroidism were not benefited by intramuscular injections of pregnancy urine extract. Four of five women younger than menopausal age were benefited by such treatment. The most marked improvement was in a moderately severe case of hyperthyroidism in a girl of 17, who was given pregnancy urine extract (antutrin-S) after and ovarian follicular hormone (theelin) before menses. After the diagnosis of hyperthyroidism was established pregnancy urine extract was given intramuscularly three times a week 1 or 2 cc, standardized as 100 rat units per cubic centimeter. The medication was given either during the fortnight preceding menstruation or that following it or continuously in all cases beyond the menopause and in some of those menstruating. The injections were discontinued when the metabolic rate fell below +10 per cent.

Surgical Treatment of Gastric and Duodenal Ulcer.—The surgical treatment that Richter presents is to be regarded as limited in its application to cases that are resistant to adequate medical care. He points out that the segment of the gastrointestinal tract including the lesser curvature and the first portion of the duodenum constitutes an organ analogous to the gallbladder. It is an organ and, whatever may be the underlying cause of ulcer, manifests itself by a lesion in that structure. The author's suggestion is to regard that structure as the organ to be removed as one would remove a gallbladder. It is a solid organ. Its surface is covered by mucous membrane. It can be removed without any more damage to the body than that of the gallbladder and its removal obviates the opportunity or ability of the ulcer to recur.

Immune Serum Production in Poliomyelitis Refractory Animals.—Schultz and Gebhardt studied the serologic responsiveness of various poliomyelitis refractory animals injected with the virus of poliomyelitis. To this end three guinea-pigs, four rabbits, one dog, two sheep, one goat and one horse were given repeated injections of suspensions of ground poliomyelitic cords over periods ranging from about six months to approximately two years. Virucidal tests were carried out on the serums of these animals at varying intervals during and after the period of more intensive virus injections. These virucidal tests were carried out by mixing 1 cc of virus suspension with an equal volume of undiluted or previously diluted serum following which the serum virus mixtures were injected intracerebrally into monkeys. Titration of the virus suspension as well as the serum was carried out on several occasions. The authors' results confirm the observations of other investigators with reference to the degree in which poliomyelitis refractory animals respond as antiserum producers, the majority responding poorly or not at all to

virus injections Individual animals may, however, respond exceedingly well A horse included in their series proved exceptionally responsive, producing a serum that contained sufficient immune substance per cubic centimeter to neutralize at least 25,000 minimal infecting doses of virus

Unusual Form of Infectious Leukopenia—Rosenthal and Kugel discuss three cases of severe infection associated with necrotic lesions of the mucous membranes and an unusual type of leukopenia Clinically these cases resembled agranulocytosis At the height of the disease, the blood picture showed a profound leukopenia with several unique features Although there was a marked depression in the total white cell count, the differential count retained the usual relations The hemoglobin, red cell count and platelets were unaffected In one case the bone marrow was found to be hyperplastic, with an abundance of mature and immature myeloid cells This is in striking contrast to true agranulocytic angina in which at the height of the disease there is ordinarily a complete disappearance of the granulocytes from the blood stream as well as from the bone marrow

Methods for Demonstration of Tubercle Bacilli—The comparison by Hirschberg of direct smear, guinea-pig inoculation and culture methods for the demonstration of tubercle bacilli in various types of specimens indicated that culture methods give a greater proportion of positive results more quickly than either of the other two methods A study of various mediums for the isolation of the tubercle bacillus proved the mediums of Corper Hohn and Miraglia to be suitable for routine diagnostic cultures Hohns and Miraglia's mediums gave larger numbers of positive results in less time than did Corper's medium Either of these two mediums may be used with equal efficiency Corper's medium however is sufficiently sensitive and becomes contaminated less often than the egg mediums and therefore should be included in routine culture methods

Barrier Between Blood and Cerebrospinal Fluid—Malamud and his associates studied the bromide distribution ratio as determined by the Walter test in 643 cases of mental disease with the following results 1 The schizophrenias showed a predominance of quotients above 320, a smaller amount ranging between 320 and 280 and few below 280 2 The psychoneuroses, psychopathic personalities and paranoid states showed a predominance of quotients between 320 and 280, with some cases above and below these limits The manic-depressive psychoses followed the same pattern but with less of the cases above 320 and more below 280 3 The toxic psychoses and the cases of untreated dementia paralytica showed quotients mainly below 280 and none above 320 In 530 of the cases the protein content of the cerebrospinal fluid was determined simultaneously with the permeability quotient and it was found that (1) there was a tendency toward a general correlation between the two values but this was not consistent, and, (2) in the cases of organic psychoses and in the schizophrenic patients, this correlation was of a higher degree than in the psychoneuroses and manic depressive psychoses

Simplified Oleothorax—Josewich feels that the simplification of technique and the use of collod materials may lead the profession to a more general acceptance of oleothorax treatment Liquid petrolatum of the best quality should be employed One may have a choice of aromatic oils or antiseptics to be added to the liquid petrolatum The author uses oil of capcut, U S P X rectified It is well to incorporate as necessary

in proper amount, various dyes or antiseptics to assist in the early detection of pleuropulmonary perforations or to add antiseptic properties to the solution. The principal change in technique is the use of a preparation in colloid form. Any disinfectant value which may be ascribed to the substances employed is based on the proposition that to be effective, a disinfectant must be absorbed by the bacteria. Since any of the injections may result in reactions, it is considered advisable to inject from 1 to 4 cc of a 1 to 5 per cent solution of the essential oil in liquid petrolatum as the initial dose. In contrast to the use of the ordinary oil, one finds in using the colloid solution that it permits the use of needles of the smallest caliber. Subsequent quantities are injected in arithmetical progression at intervals of one week or longer. If pus is present, moderate amounts should be removed at each treatment. One must not be over-enthusiastic about obliterating the pneumothorax pocket, as the persistence of a small air pocket serves as a buffer in the event of increased hydrostatic pressure due to the production of exudates resulting from irritation of the pleura by the oil. This lessens the possibility of perforation and tearing. The most reliable means of checking the status of the oleothorax is fluoroscopic control before and after the injection of the oil, as well as in the interim. Manometric readings are usually obtained, but they may be and frequently are misleading and subject to alarming change within a few minutes or hours.

Refinement in Coagulation Time Technic—Hochstetter points out that the disadvantages of the accepted method of determining the coagulation time of blood may be overcome by drawing the blood about half the length of a rather large bore capillary tube. In place of breaking the tube at intervals of fifteen seconds the tube is inverted at intervals of fifteen seconds and the time is noted when the column ceases to flow. This is recorded as the coagulation time. In checking the foregoing modification, the author performed determinations by both methods on fifty neuropsychiatric patients chosen at random. The lowest time recorded was one minute and fifteen seconds by both methods, and the highest time was four minutes and thirty seconds by both methods. In twenty-nine instances the coagulation times were identical by the two methods. In nineteen instances the coagulation times were fifteen seconds shorter by the gravity method. In two instances the coagulation time was fifteen seconds shorter by the fracture method. It should be noted that in no case did the discrepancy exceed fifteen seconds.

Type I Pneumococcal Infections Specific Serum Treatment—The results of Sutliff and Finland and those obtained by other observers leave no room to doubt that concentrated type I antipneumococcus serum exerts a striking

symptomatic effect and reduces the death rate by one half in type I lobar pneumonia in adults. Repeated studies have also shown that the effects are type specific, that treatment early in the course of the disease is more effective than later, that treatment is equally effective at all ages, and that bacteremia as a symptom and bacteremic cases as a group are especially amenable to specific therapy. The results that may be expected in patients treated before the end of ninety six hours of illness may be briefly summarized as a marked symptomatic change in two thirds of the recovered patients within thirty six hours of beginning treatment and a death rate approximating 10 per cent.

Pancreas as a Blood Pressure Regulator—To determine the relation of the pancreas to blood pressure, Halprin observed nine patients having old arteriosclerosis with nephritis, aortic disease or essential hypertension. They complained of occipital headache, dizziness, spots in front of the eyes and shortness of breath. They were permitted to go one week without medication but were given a regular diet, when they returned to the clinic the following week they were given a diet that was salt poor and high in carbohydrate. In addition, each patient was given a 4 ounce bottle of a pancreatic extract, for oral use, prepared especially for this purpose from the fresh (not frozen) gland without heating, drying or using alcohol extractives. This pancreatic substance given to a normal patient whose blood sugar was 120, on a starving stomach, reduced the blood sugar to 100 after a breakfast of one orange, a bowl of cereal, two eggs two rolls and butter. The patients were told to take 2 drachms of the extract in milk or water with each meal. Those who were unable to follow the diet were advised to eat their regular daily meals and to add three oranges or three apples to their diet. The result after one month showed that each patient lost from 2 to 4 pounds. They all felt generally better, headaches were less. Blood pressures invariably showed a drop in the diastolic pressure to below 100. Four patients showed a drop of from 10 to 20 mm of mercury in the systolic pressure after five months. All these patients are symptomatically better, all express themselves as feeling better now than in the past one or two years. The diastolic pressures have stayed lower and the systolic pressures have either remained unchanged (in the old sclerotic cases) or dropped from 10 to 30 mm of mercury in the cases of essential hypertension and have remained so. The patients were picked at random in the cardiac clinic of the author's hospital.

Treatment of Cancer of Lip by Electrocoagulation and Irradiation—Pfahler and Vastine state that successful treatment of carcinoma of the lip consists in early adequate destruction. Early cases with no palpable nodes are treated by surrounding the lesion with a line of local destruction by electrodesiccation, after local anesthesia with procaine hydrochloride, then the removal of a specimen for biopsy and immediate destruction of the remainder of the primary growth. This is all done at one time. Removal of the primary growth is followed by the administration of high voltage roentgen rays generated with 200 kilovolts and filtered through 0.5 mm of copper, directed through the lip the submaxillary and submental regions, producing a crossfiring effect on the cervical nodes. This irradiation is given in repeated doses until a total of about 1,400 roentgens has been administered through each portal, the saturation (Pfahler) technic being employed. In lesions of the upper lip with no palpable nodes, it is important to irradiate thoroughly through lateral fields as a prophylactic measure. Extensive lesions, greater than 1.5 cm in diameter, require greater individualization of the treatment. In extensive lesions in which destruction by electrocoagulation is not practical, radium element, administered both interstitially and on the surface is employed. A filtration of from 0.3 to 0.5 mm. of platinum is employed in the radium needles for interstitial use and a filtration of 2 mm. of platinum is used in surface applications. The number of milligram hours depends on the size of the lesion. High voltage roentgen therapy is administered to the regional areas of lymph drainage either alone or combined with radium packs at a distance of from 4 to 6 cm. depending on the presence of palpable lymph nodes. If there is manifest disease in the nodes surface applications of radium

are combined with interstitial irradiation by means of needles of radium element inserted about the diseased nodes. The authors employed the foregoing methods in 275 cases of epithelioma, 226 of the patients are living and are free from evidence of the disease, thirty-nine are dead and ten were well when seen last but could not be traced.

New Treatment of Osteomyelitis—Stewart experimented to determine how maggots cure osteomyelitis. He made extractions of living sterile maggots using water, alcohol, acetone and other chemicals as extracting agents. It was found that maggots (*Lucilia sericata* Meig) exude calcium carbonate through their body walls. 100 maggots will excrete an average of 0.6 mg of this substance every twenty four hours. Calcium carbonate was eliminated constantly into the wound. Calcium ions stimulate phagocytosis. The leukocidin excreted by the bacteria had to be eliminated rapidly or rendered inert otherwise the phagocytes would be killed about as rapidly as they appeared at the focus of infection. This the author attempted by experimentation on animals with a 0.25 per cent saturated aqueous solution of trinitrophenol containing 8 per cent glycerin and also an autoclaved aqueous suspension of calcium carbonate, 20 Gm of calcium carbonate to 215 cc of distilled water. The technic consisted of removing the necrotic bone surgically, the excavation being made long and as narrow as possible so that the strength of the shaft may be retained and so that the cavity might close much more quickly. Following the operation the wound is packed for twenty four hours with petrolatum gauze.

in order to allow the trauma to subside somewhat. At the end of this period the packing is removed and the wound is thoroughly irrigated with the trinitrophenol glycerin solution by means of a syringe. This solution penetrates quickly to every crypt in the wound and thereby gains access to the leukocidin and some of the bacteria as well, and within a few seconds an aqueous suspension of calcium carbonate is sprayed into the wound by means of a nasal atomizer until a thin layer of precipitate is laid down over the osseous and soft tissues. The calcium carbonate combines with the trinitrophenol solution and forms calcium picrate. The trinitrophenol is given an opportunity to reach the greater quantity of the leukocidin and apparently acts on it immediately, and then as the calcium carbonate is added, forming calcium picrate, the calcium ions are rendered available to stimulate phagocytosis. Calcium carbonate controls acidity by maintaining a neutral or even alkaline condition, the degree of which depends on the condition of the wound and the amount of calcium carbonate present. The author has observed in twenty-eight cases that the rate of drainage increases rapidly, thereby inhibiting the dangerous pushing back, into the rigid bone of the defensive barrier as well as removing debris. Moreover, calcium picrate has very definite analgesic properties with consequent relief to the patient. After the calcium carbonate suspension is applied the wound is packed with dry gauze in order to prevent closure. When the foci of infection are deep the trinitrophenol solution and the calcium carbonate suspension are applied through Dakin tubes with the ends cut off, or through male catheters, which are placed in the wound and packed in place with petrolatum gauze or pushed down through the sinus tracts as needed. Ordinarily these treatments are given three times a week, but in severe acute cases they are usually given daily for the first week or two. In every instance improvement has been clearly observed in not more than a week after the first treatment. After the first week of treatment the drainage usually becomes less copious, bone destruction is arrested and the soft tissue shows healthy granulations. Frequently in cases of osteomyelitis of the tibia a sloughing of the soft tissue occurs after the wound has been granulating for some time. In an attempt to check this sloughing an aqueous suspension of one part of thiophenol and ten parts of distilled water may be applied to the wound with a cotton applicator. The water is boiled before the thiophenol is added in order to eliminate the free oxygen. One, and at the most three, applications suffice to check the sloughing, and granulation continues as before.

Diagnosis of Trichomonas Vaginalis Vaginitis—Ewing and LeMoine state that *Trichomonas vaginalis vaginitis* can be diagnosed from a dry smear by a simple phenol fuchsin stain. In making phenol fuchsin stains, thin smears are made. They are fixed in air not fixed; the slides are covered with phenol fuchsin (about 20 to 25 drops), 20 drops of distilled water are added and allowed to stand for three minutes; the slides are washed with distilled water and dried between filter or blotting papers, and the examination is made under an oil immersion lens. Two dry smears and a hanging drop are taken in every case. One dry smear is stained by the usual gram stain method and the other by phenol fuchsin. A diagnosis is made from these before the result of the hanging drop, done by another technician, is known. Of ninety smears examined, 66 per cent were found positive and 34 per cent were found negative for *Trichomonas vaginalis* of these ninety smears the hanging drop examinations were positive in 41 per cent and negative in 51 per cent. In 8 per cent of the cases, no hanging drop examination was made. Positive observations in hanging drop examinations were shown in only 63 per cent of the cases with positive smears.

Flap Operation for Treatment of Acute Empyema Thoracis—Nicoll offers a flap operation for the treatment of acute empyema which he believes has the following points to recommend its use: 1 It is physiologic in that it takes into consideration the normal condition of negative pressure within the pleural cavity. 2 It is a closed method of drainage and remains so from the beginning to the end of treatment. 3 It affords adequate drainage because of a generous opening into the pleural cavity made possible by rib resection, with the fur-

ther "reaming" action of drainage apparatus. 4 It permits early operation in empyema before adhesions in abnormal positions of the lung have occurred, without the dangers resulting from "mediastinal flutter" and collapse of compressed lung. 5 It can be done under local anesthesia in adults, the youngest patient was 13. 6 Because it is completely a closed drainage, it can be done safely in children under ether anesthesia. 7 It abruptly cuts short the sepsis due to undrained or incompletely drained pus, thus relieving the organs of excretion of their overheavy burden. 8 It shortens convalescence. One case was entirely healed in ten days, in spite of a chest that held the maximum of pus at operation. The author presents a summary of thirty-five cases in which he employed the flap operation.

Functional Hyperparathyroidism—Leopold reports five cases of hyperparathyroidism in all of which the following clinical syndrome is exhibited: insomnia, vasospastic phenomena, anorexia, absent or greatly diminished reflexes, weakness, myotonia, subacidity or acidosis, in most cases decreased or absent circulation of the extremities, pains in the legs and bones, and polyuria. In treating these cases calcium gluconate has been given as a routine, usually 15 Gm daily, the amount being gradually reduced as the blood calcium became lower. Acidosis has been managed in the usual fashion, with acid orally. High calcium diets have been used. Cod liver oil products and ultraviolet therapy have been avoided. Rest and massage have been emphasized and irradiation was used in one case. It has been particularly interesting to note the return of reflexes, the correction of insomnia and parallel stabilization of parathyroid activity as measured by blood calcium estimations. Thyroid administration was strictly avoided in these cases, and basal rates estimated in several cases on apparent recovery became normal without its use.

*Increased Intra Ocular Tension in Young Persons as a Cause of Severe Frontal Headache R L Raymond—p 102

Sympathetic Ganglionectomy for Gangrene Due to Thrombo-Angitis Obliterans—Stewart reports a case of gangrene due to thrombo-angitis obliterans in which both upper limbs were saved from gangrene by sympathetic ganglionectomy. Both lower limbs had been lost previously from the disease. The posterior route through the chest for the removal of the inferior cervical and first thoracic ganglions, is considered to be better than the anterior approach. The exposure is superior, and incomplete removal of the first thoracic ganglion, liable to occur by the anterior route, is by this means unlikely. The removal of these ganglions on both sides was not accompanied by any permanent ill effects on the brain, eyes or heart.

Increased Intra-Ocular Tension as Cause of Headache—Raymond presents four cases with the belief that they represent a symptom complex that is not commonly recognized. Each patient complained of frontal and temporal headache of varying degree and radiation, each was a young man between the ages of 20 and 30, and before the typical glaucoma age. In each case frontal sinusitis, tic douloureux, incipient herpes ophthalmicus, migraine, and so on, were considered and as far as possible eliminated. In each case the pain was increased by pressure on the eyeball, and the tension of the eyeball, as estimated by digital examination, was thought to be higher than that in the other eye. There was no other constant abnormality in the eyes. The pupils, except in one case, were equal and round and reacted equally to light. Visual acuity was normal to the individual patients. Two patients resented the glare of the ophthalmoscope, and the author was unable to see the disk. Homatropine was avoided for fear of increasing the symptoms. The author has since examined the fundi of each patient under homatropine. Acting on the assumption that this increased intra ocular tension might be the cause of the referred neuralgia, scopolamine was instilled into the eye in each case, with the result that the condition cleared up in from five weeks to three months. There was one recurrence.

Hematopoietic Response to Injections of Gastric Juice—Fouts and his associates state that their studies indicate that some change in fresh human gastric juice must take place before a hematopoietically active material can be demonstrated by the intramuscular injection into patients with pernicious anemia. 1 During the process of vacuum distillation the intrinsic factor acts on an extrinsic factor present in the gastric juice in too small amounts to be active when fed by mouth. The intrinsic factor is known to be present in fresh human gastric juice and has been demonstrated by the authors in another group of experiments to be present at the onset of the vacuum distillation in all the preparations that were made active by this procedure and in none of those that were not so made active. 2 During the process of concentration by vacuum distillation a material irritating or toxic to the hematopoietic system is produced. The prolonged and delayed reticulocyte response, the marked bone marrow irritation the delayed rise

in red blood cells and the fact that each patient who responded to the injection of the concentrated gastric juice had a more or less severe reaction suggest this possibility. One of the authors' cases is of especial interest in that after the injection the temperature rose to 106 F, the red blood cell count decreased 0.55 million and there was an increase in icterus. There was no rise in red blood cells until after a prolonged reticulocytosis. 3 During the concentration by vacuum distillation, a hormone is released or activated. In their opinion the hematopoietically active substance must be formed by the action of the intrinsic factor on an extrinsic factor in the gastric juice, or by the production of a substance irritating or toxic to the hematopoietic system.

Familial Chondrodystrophy Treated by Roentgen Therapy—Hilton discusses the case of a girl of 10 presenting deficient growth and painful tumors at the lower end of both femurs, the roentgen appearances were those of a rheostosis of certain bones, together with signs of chondrodystrophy. Histologic appearances are described. The mother of the patient and two maternal aunts are also affected. The name suggested for the syndrome is familial chondrodystrophy with multiple rheostoses. The differential diagnosis is made from (1) melorheostosis, (2) metaplastic and hyperplastic malacia, (3) ossifying periostitis, (4) osteoblastic osteogenic sarcoma, (5) multiple exostoses (diaphyseal aclasis) and (6) osteopathia hyperostotica multiplex infantilis. The response to roentgen therapy was rapid and satisfactory.

Celiac Disease in an Adult Treated with Sugarless Milk, Bananas and Meat—Roberts treated a case of celiac disease in an adult by putting the patient on a sugarless milk, banana and meat diet. The ordinary forms of carbohydrate were absent. Although such carbohydrates themselves are absorbed and were at no time found undigested in the feces, they appear to arouse the symptoms of celiac disease including interference with calcium metabolism and resulting tetany and impairment of the utilization of other foodstuffs. The banana is helpful in celiac disease. Its carbohydrate can be used it seems, indefinitely without giving rise to the symptoms of the complaint, which is not the case with other carbohydrates. With the banana the proportion of carbohydrate protein and fat can be balanced satisfactorily and utilized. The diet when established has a high fat content most of which was absorbed. In a research on another patient passing large fatty stools it was found that milk fat was more easily absorbed than other forms of fat. When this patient recovered fifteen years ago on a meat diet it was then possible to use ordinary general foods beginning with bread and butter in moderation. The same is found in other cases of this disease on the regimen described by the author. It is important, however not to try such an addition until after at least six months of health on the special diet.

Sighing Respiration as a Symptom—Baker describes a disorder of breathing that is so common as almost to have

passed unnoticed in symptomatology. It affects patients without physical signs of disease and is generally associated with a group of symptoms expressive of physical or nervous exhaustion. The disorder is frequently described by patients incorrectly as "breathlessness." The importance is shown of inquiring into the character of the breathlessness, as, if of the "suspirious" type, it will aid in assessing the part played by the nervous system in whatever condition may be found, particularly in those cases in which it may happen to be associated with organic disease. If, however, the patient's statement is accepted without inquiry the resulting misinterpretation of the symptom will confuse the diagnosis. Degrees in the severity of this symptom from an occasional forced sigh to an attack lasting for hours or even days are illustrated by four typical cases. The etiology is obscure, but it has been suggested that it is associated with a spasm of the diaphragm. In support of this is the fact that the end of each inspiration is achieved with effort as if against some obstruction and further that constriction of the thorax or the abdomen gives rise to deepening of respiration. The absence of any organic basis for the disorder makes prognosis as to life good, but the symptom is often resistant to present forms of treatment and is liable to recur with recurrence of nervous stress or ill health. All the evidence points to this disorder as being of nervous origin, and in no circumstances is there an indication of cardiovascular disease.

Method of Injection of Facial Nerve.—Whillis outlines a method for the injection of the facial nerve which aims at injection of the trunk of the nerve just as it leaves the stylomastoid foramen. After preliminary infiltration of the skin with procaine hydrochloride the needle is entered just behind and about one-fourth to one eighth inch above the tip of the mastoid process of the temporal bone. A few minims of procaine hydrochloride is injected and the needle is pushed on in close contact with the deep surface of the mastoid. The point to be aimed at in both upward and inward directions is the nasion. Having reached a depth varying between 1 and 1½ inches, the point of the needle will be felt to strike the base of the styloid process. The needle is now withdrawn slightly and the point tilted upward so as to engage in the stylomastoid foramen. When this has been reached fairly severe facial spasms usually occur. The immediate abolition of these spasms by the injection of a few minims of procaine hydrochloride gives a dramatic indication that the nerve has been reached. Another syringe containing alcohol is attached and a small quantity injected into the nerve. It is important in carrying out this method to aim exactly for the nasion, as, if the needle passes too far medially, it misses the styloid and may enter the internal jugular vein. It is safer before making any injection to make sure that this has not happened by attaching an empty syringe to the needle and aspirating gently.

*Calcium and Phosphorus Metabolism in Diseases of Thyroparathyroid Apparatus. Part I. Calcium, Phosphorus and Total Metabolism in Hyperthyroidism and the Part Played by Parathyroid Glands. F. S. Hansman and F. H. Wilson—p. 37

Calcium and Phosphorus Metabolism in Diseases of Thyroparathyroid Apparatus.—Hansman and Wilson state that the thesis of Aub and his co-workers and that of Hunter that thyroxine has a direct catabolic effect on the calcium deposits in the bones cannot be accepted on the evidence they present. The authors observed seven patients suffering from hyperthyroidism, and an analysis of their experimental data provides definite evidence in favor of an associated hyperparathyroidism being the direct cause of the excessive mobilization and excretion of calcium and phosphorus. Two patients suffering from hyperthyroidism presenting an associated hypoparathyroidism were studied. Both patients were in calcium and phosphorus equilibrium. Hyperthyroidism is frequently but not invariably accompanied by a negative calcium and phosphorus

balance. It is possible for calcium and phosphorus equilibrium or a positive calcium and phosphorus balance to be present. Hyperthyroidism alone has no specific effect on calcium and phosphorus metabolism. The authors were unable to confirm the observations of Aub and his co-workers and of Hunter that the excretion of the mobilized calcium is predominantly fecal. Their experimental results showed that, if hyperthyroid patients receive a diet that satisfies the special requirements of the hyperthyroid state, the mobilized calcium and phosphorus are excreted in a similar manner to that obtaining in other diseases associated with a negative calcium and phosphorus balance.

Peripheral Neurolymphomatosis.—The case of a woman, aged 67, showing symptoms of peripheral nerve disease is described by Lhermitte and Trelles. Both median nerves were irresponsive to the electric current. All signs indicated a degenerative change in the nerves of the forearm and hands involving both sensory and motor tracts. The patient died of bronchopneumonia. A necropsy revealed increase in size, irregularity and cottony feeling of both median nerves. Examination of the viscera revealed only atherosclerosis with nephrosclerosis, a liver slightly cirrhotic and a slight increase in the size of the spleen with visible malpighian follicles. Histologically a lymphoblastic infiltration of the median nerves was found strictly localized to the antibrachial and carpal portions of the nerve. The authors conclude from other studies of neurolymphomatosis that it is related to an infectious process. It is not yet possible to settle the morphology of the causative virus. All that can be said is that the virus placed in contact with glycerin is destroyed in nine days in the icebox.

Technic of Resection of Knee.—Sabadini describes his technic for resection of the knee in tuberculosis. The skin over the anterior portion of the knee is incised at about the level of the lower border of the patella. The skin over the patella is dissected back and the quadriceps tendon and ligaments are sectioned. The femur is sawed from front to back and the dissection continued posteriorly without opening the capsule of the knee. Finally, the tibia is sawed through from back to front and the entire joint can then be removed without having been opened. The cut surfaces of femur and tibia are placed in apposition either with or without a metal joint. The cut quadriceps femoris is sutured to the vastus and the fascia lata and especially to the pretibial aponeurosis. Finally the skin is sutured in a horizontal line. The author has obtained excellent results with this procedure and feels that the only contraindication is the general condition of the patient.

Cervical Adenopathies and Pulmonary Tuberculosis.—Campani studied 138 patients with purulent processes of the cutaneous or mucous membrane, e.g., acne vulgaris, who developed homolateral tuberculosis. These patients could be divided into seven categories. The first group (consisting of forty-one cases) presented a pyogenous process with cervical lymphatic reaction in the region of the head. The second (thirty-seven cases) presented chronic suppurations of the upper limb with axillary adenitis. The third (four cases) included septic processes of the throat. Oral sepsis and infections of the mouth and teeth comprised the fourth group. The fifth included otitis and suppurations of the external ear. The sixth and seventh groups were suppurations of the eye and scrofulous manifestations in the neck, respectively. The author feels that these studies help to confirm certain laws. These are the laws of the absolute numerical predominance of scrofulous cervical adenitis over all other adenitides of the same nature, the law

of the frequency of preceding homolateral septic lesions, the law of victory and evolutionary character of the pulmonary process as opposed to the preexisting superficial septic cutaneous processes and, finally, the law of the pathologic binomial following which the tuberculous reinfection is the fact of a concurrence with another local morbid state, especially of septic nature, and always involving the lymphatic routes

Tuberculous Infiltrates—According to Spiro, it was Redeker who first advanced the theory that the development of tuberculous infiltrates is the manifestation of an allergic condition, that is, of an exogenous or endogenous sensitization. The author was able to corroborate Redeker's opinion by laboratory methods. He found that infiltrative tuberculosis a term under which he combines early infiltrates, late infiltrates and the so-called secondary infiltrations, is characterized not only by an allergic change in the blood picture by eosinophilia but also by typical allergic changes in the alimentary blood sugar curve. The latter is characterized by a slightly retarded ascending line and by a noticeably heightened apex. The fact that the same changes are also occasionally noticeable in caseous cavernous tuberculosis but not in productive-indurative tuberculosis makes it appear probable that the infiltrative tuberculosis, as regards its immunobiologic basis, is a preliminary stage of caseous-cavernous tuberculosis.

Incidence of Tuberculosis of Oral Mucous Membrane with Open Cervical Glands—Burckhardt and Bahl describe the histories of fifteen children with tuberculosis of the oral mucous membrane. They detected this number among sixty eight children with open cervical glands. This is a comparatively high incidence. The occurrence of nodules in a slightly reddish mucous membrane is particularly suspicious of tuberculosis, and the authors think that this ulcerous, miliary tuberculosis or gingival miliary tuberculosis is often overlooked and they advise that more attention be given to it. The disorder seems to be connected most frequently with dental caries, suppurations of the roots, dental fistulas or parodontitis. The infection may be either exogenous or hematogenous (more probably the latter). It appears that nonspecific dental disorders also exacerbate and prolong tuberculosis of the cervical lymph nodes. The authors advise that in children with tuberculosis the teeth and the mouth be given attention and treatment given if it is required, and that even the deciduous teeth be cared for.

Phrenicectomy as Substitution for Pneumothorax—Froehlich presents three case reports in which pneumothorax proved unsuccessful and in which cure was effected with phrenicectomy. He thinks that occasionally it is preferable to substitute phrenicectomy for an ineffective pneumothorax particularly when the latter has to be improved by the detachment of numerous adhesions, a method that is often hazardous and not without danger.

Relation Between Basal Metabolism and Erythrocyte Sedimentation Rate—Goldemberg found a direct relation between the basal metabolism and the erythrocyte sedimentation

rate in 77 per cent of the patients suffering from hyperthyroidism, that is, the increase of the basal metabolism corresponded proportionally to that of the erythrocyte sedimentation rate. In 69 per cent of the group of persons with normal thyroids the basal metabolism and the erythrocyte sedimentation rate were normal. The erythrocyte sedimentation test (Farhacus's test) may serve as an aid to the test of the basal metabolism for the serial study of the effects of fluoride therapy (Goldemberg) or roentgen therapy (Tateka and Goldmann) in patients suffering from hyperthyroidism. The diagnosis of hyperthyroidism cannot be based only on the presence of a high sedimentation speed of the erythrocytes if the clinical symptoms, which are the most important are not taken into consideration, because the speed of the sedimentation may be due to many other causes, such as cancer, pregnancy, the presence of bacillary or other infections and syphilis. The erythrocyte sedimentation caused by hyperthyroidism is of a moderate velocity and ranges from 14 to 45 mm during the first hour, while that due to extrathyroid conditions is higher and may even reach 120 mm in the first hour, as seen in carcinoma. A hyperthyroidism with high basal metabolism and high speed of the sedimentation rate is of grave prognosis and reacts to the treatment by fluoride slower than hyperthyroidism with elevated basal metabolism and normal erythrocyte sedimentation rate. A normal sedimentation of the erythrocytes does not exclude, by itself, hyperthyroidism, but it does so when associated with a normal basal metabolism.

Influence of Experimental Dermatitis on Internal Organs—Milbradt observed after extensive chemical and physical cutaneous inflammations characteristic disturbances in the carbohydrate metabolism, that is, a tendency to increased blood sugar values during fasting. He interprets the more pronounced Staub-Traugott effect not as an increased functional activity of the pancreas but rather as an impairment of the liver. The impairment of this organ is made still more probable by the outcome of Althausen's test, by the epinephrine tolerance test and by an increased arsphenamine susceptibility. In herbivorous animals (rabbits and guinea pigs) the liver is the organ that becomes most easily impaired. The kidney on the other hand, so far as its functions could be determined on the behavior of the rest nitrogen becomes insufficient shortly before death when it no longer can eliminate the waste products of protein metabolism. Uric acid and amino acids are generally reduced. In the blood a considerable disintegration of cells takes place for the erythrocytes decrease gradually and there are signs of strong regeneration such as polychromatophilia vital granulation and young forms. In the beginning the aspects of secondary anemia predominate. Only during the phases of spontaneous remission does the color index increase occasionally above the initial value. During the later stage there develops a toxic impairment of the erythropoietic

apparatus, indicated by anemia and the absence of signs of regeneration. The blood, on the other hand, shows a considerable leukocytosis with relative or absolute lymphopenia and shows no impairment even at the end. The author's investigations indicate what metabolic disturbances may develop secondarily in extensive dermatoses. He emphasizes that these investigations do not permit generalizations and that it would be wrong to consider all such metabolic disturbances as secondary. His investigations indicate only possibilities. The real connection between cutaneous and metabolic disturbances must be studied in each case by careful clinical analysis. The author's studies, however, opened interesting perspectives on the connections between each other due to protein bodies death from extensive experimental dermatitis and death from burns.

Clinical Investigation on Porphyrin—Fikentscher and Franke point out that, since it has been proved that porphyrin plays an important part in blood pigment metabolism, a number of methods have been devised for its quantitative and qualitative determination. The authors show that satisfactory quantitative values can be determined with the spectrophotometric method of Selum, Schreuss and Caric and with the measurements of luminescence according to Fikentscher or according to Hyman van den Bergh and Grotpass. The authors state that the method of Fikentscher, which is based on the characteristic red fluorescence in the ultraviolet is the most sensitive. It makes possible the detection of as little as 1 microgram per hundred cubic centimeters in the hydrochloric acid extract. Moreover, the method requires only small quantities of material. For the quantitative determination of ether soluble porphyrins in the urine the authors describe special measures. The daily elimination of porphyrin in the urine ordinarily does not exceed 30 micrograms. The determination of the exact type of the porphyrin encounters considerable difficulties in the clinical examinations. The ideal method is the chemical analysis described by W. Fischer, but it has the disadvantage that it requires larger quantities of porphyrin than those available in clinical examinations. The authors describe a method that permits the use of the smallest amounts of porphyrin and employs the simple apparatus of the quantitative luminescence analysis. The method is based on a procedure described by Fink, which permits the identification of the various porphyrins by means of the so-called pH fluorescence curves.

Diagnostic Value of Cholesterol Tolerance Test—Barreda duplicated Burger's cholesterol tolerance test on eighteen persons without metabolic disturbances. The technique of the test is as follows: The person to be tested is given 5 Gm. of cholesterol, dissolved in 100 cc. of hot olive oil, while the stomach is empty. On the day of the experiment and also on the preceding day the person receives a diet that has a low fat and cholesterol content. Specimens of blood are withdrawn before the intake of the cholesterol and also four, eight and twenty-four hours after the intake. The serum of these specimens is then examined for free cholesterol and for the total amount of cholesterol. On the basis of this tolerance test, Burger and his collaborator reached the conclusion that in persons without metabolic disturbances there always develops

a hypercholesterolemia. Barreda, however, reaches the opposite conclusion, for in none of the normal persons tested by him did the cholesterol content increase following the ingestion of the cholesterol, and he maintains that the outcome of this tolerance test does not permit a definite estimation of the condition of the cholesterol metabolism.

Chemicohormonic Pregnancy Reaction in Mares—Cuboni points out that the hormone content of the urine of pregnant mares differs from that of pregnant women in that the urine of mares shows a predominance of the follicular hormone over the hypophyseal hormones, the follicular hormone amounting to from 90 to 95 per cent of the total hormone content. This observation and the fact that in mares the biologic pregnancy test encounters certain difficulties induced the author to employ a chemical reaction for the diagnosis of pregnancy in mares. The test is based on Kober's observation that a fluorescence appears on treating the follicular hormone with bent and with concentrated sulphuric acid. After the urine has been filtered, 1 cc. of concentrated hydrochloric acid is added to 5 cc. of the urine, and the test tube containing this mixture is placed for ten minutes in the boiling water bath. Then, after the test tube has been cooled under the water tap, 6 cc. of benzene is added. This mixture is shaken, the urine is drawn off, and the layer of benzene above it is gathered in a tube and, if necessary, is filtered through paper. Of this benzene extract 3 cc. is then dried and to the residue is added 0.8 cc. of concentrated sulphuric acid. This is heated for several minutes in a water bath of from 70 to 80 C. and the results are read. In case of a negative reaction (absence of pregnancy) the fluid shows either the red coloration of malaga wine or reddish brown or brown and is never fluorescent. In case of a positive reaction (presence of pregnancy), the fluid, when observed while the light shines through it may show one of the aforementioned color nuances, but if observed while the light falls on it, for instance if the observer turns his back to the window, a clearly greenish coloration becomes visible through the fluorescence. The author emphasizes that the reaction is inexpensive and can be completed in from fifteen to twenty minutes. Tests on thirty-five pregnant mares gave 100 per cent positive results. In nonpregnant mares, in castrated animals and in stallions the results were 100 per cent negative.

Treatment of Malignant Tumors by Roentgen Rays Adapted to Radium Rays—Chaoul points out that radium rays are superior to roentgen rays in the treatment of tumors. This superiority of radium treatment is noticeable particularly in tumors of the lips, the tongue, the buccal mucous membrane, the floor of the mouth and the female genitalia. Since the supply of radium in German hospitals is less than 9 per cent of the amount that is required if the accepted standard of 25 Gm. per million of population is accepted, efforts were made to adapt roentgen rays so that their action would be like that of radium rays. To accomplish this changes had to be made in the time factor, in the spatial distribution of the rays and in the dosage. The author shows that Coutard's method of fractional, protracted roentgen irradiation, which gave attention to the time factor, was the first step in the adaptation of the roentgen to the radium rays. To adapt the spatial distribution of roentgen treatment to that of radium therapy, it was necessary to limit the ray action both in surface and in depth. This

was done by reducing the focus distance to 4 cm, applying the rays to smaller fields and using softer rays. The author found that a tube tension of from 50 to 100 kilovolts and filtration through 1 mm of aluminum or 0.5 mm of copper are equal to all requirements. The third factor that has to be considered in the adaptation of roentgen to radium rays is the increase of the total dosage. In combination with the other adjustments this was readily possible, for total doses of from 15,000 to 20,000 roentgens were administered (with intercalation of rest periods) and were tolerated without serious impairment. The retrogression of the tumors generally set in at the end of the treatment, rarely before from 4,000 to 5,000 roentgens had been applied. The author employed this modified roentgen treatment in fifty-eight cases, with complete freedom from symptoms in fifty-five. This result appears the more favorable when it is considered that in more than half of the cases the cancers were of the severest type.

Treatment of Hemorrhages from Gastric or Duodenal Ulcer—Friedemann objects to the standpoint taken by Schlecht, who expressed the opinion that an acute severe hemorrhage from a gastric or duodenal ulcer is never an indication for immediate surgical intervention because the operative mortality is high, while a fatal hemorrhage is extremely rare. He gives case reports showing on the one hand that fatal hemorrhage is not unusual if an expectant attitude is assumed and on the other hand that the operation is not as dangerous as has been assumed. However, it is not the author's aim to recommend surgical treatment as the only suitable one for bleeding ulcers.

Flocculation Test for Malaria—Voigtlander considers Henry's flocculation reaction for malaria particularly valuable because this test gives positive results in acute chronic and latent cases. The test is a specific antigen-antibody reaction. The plasmodia of malaria destroy the erythrocytes and transform the hemoglobin into melanin which contains iron. The melanin, serving as antigen is prepared from the choroid of the eyes of oxen. The author thinks it best to use a ready prepared antigen. Five test tubes are used for the examination. The first one contains 0.1 cc of serum and 0.5 cc of melanin A (melanin A consists of 0.05 cc of the original antigen and 0.45 cc of redistilled water). The second tube contains 0.1 cc of serum and 0.5 cc of melanin B (melanin B having half the concentration of melanin A). The third tube (control) contains 0.1 cc of serum and 0.5 cc of redistilled water that has been treated with solution of formaldehyde. This so-called formalized water is prepared by mixing 200 parts of water and 1 part of a 35 per cent solution of formaldehyde and by adding to 0.05 cc of this 0.45 cc of redistilled water. The fourth tube contains 0.1 cc of serum and 0.5 cc of melanin A. Melanin A

consists of 0.05 cc of the original antigen, plus 0.05 cc. of a 0.6 per cent solution of sodium chloride plus 0.4 cc. of a 0.3 per cent solution of sodium chloride. The fifth tube (control) contains 0.1 cc of serum and 0.5 cc of formalized sodium chloride solution. The latter is prepared from 0.05 cc of a formalized 0.3 per cent solution of sodium chloride plus 0.45 cc of a 0.3 per cent solution of sodium chloride. The tubes are placed for two and one-half hours into a water bath of 37° C and then they are kept at room temperature for another half hour. The reaction is read by means of the agglutinoscope. In case of a positive reaction, tubes 1, 2 and 4 show flocculation, but in weakly positive serums the flocculation may appear only in the first tube. If autoflocculation of the serum is absent, the sediment is finely flocculated. But if there is autoflocculation, the finely flocculated sediment that is specific for a positive reaction is covered by the coarse floccules of the autoflocculation. In these cases the control in the formalized refracted water likewise shows flocculation, and only the reaction in the sodium chloride solution is demonstrative. If the sodium chloride control should also show flocculation, Henry advises an increase in the sodium chloride content, but the author has never found this necessary. The positive flocculation looks in the agglutinoscope like snowflakes. Diffuse, veil-like precipitates or finely granulated flocculations are non-specific. The author studied this test on 224 serums. He obtained positive reactions in acute malaria in human subjects, and in acute latent and chronic malaria in canaries. In persons with other diseases the reaction was generally negative, but in a patient with secondary syphilis a positive result was obtained. In canine piroplasmiasis and in other animal diseases that resemble malaria (Halteridium infection) the reaction was negative. In malaria therapy of patients with dementia paralytica, the test gave a comparatively exact picture of the development. The reaction was negative before the inoculation, during the incubation and during the first two attacks. After the third attack it became positive. Following completion of the malaria therapy it became gradually weaker and reached the zero point after from four to six weeks.

Pathogenesis of Goat's Milk Anemia—Gorgy points out that a one-sided milk diet often causes in nurslings and small children more or less pronounced anemic blood changes. It has been observed that feeding with goat's milk results in anemia more often than does feeding with cow's milk, and leads to it more rapidly, that is the latent period is shorter. Goat's milk anemia is hyperchromatic and the author assumes that it resembles pernicious anemia in still other symptoms. Iron or iron and copper have no effect on goat's milk anemia but it yields to liver therapy in a comparatively short time even if the goat's milk feeding is continued. Goat's milk anemia as a rule is not accompanied by achylia so that the gastroenteric theory of pernicious anemia cannot be applied to it. However its genesis is closely related to the deficiency of the so-called extrinsic factor of Castle—occasionally accompanied by lack of iron. This theory of pathogenesis is borne out by the fact that goat's milk anemia responds not only to liver therapy but also to yeast extract.

Prodromal Angina of Measles—Mayerhofer differentiates the prodromal angina of measles from the angina morbillosa known to the older physicians and from the tonsillitis of measles described by Grumann. He considers the two latter forms identical but shows that his prodromal form differs from them in that they develop during the period when the exanthem first appears, while his prodromal form develops much earlier. He shows that a careful study of the incubation period occasionally reveals a fever curve with several peaks. The first attacks of fever (first to fourth day) after the infection represent in measles just as in some other infectious diseases, the primary, that is the nonallergic initial fever. After the fourth day new temperature increases may develop and the author considers them allergic, particularly in those cases in which they appear combined with the prodromal angina of measles. This condition develops not often between the fourth and eighth days after infection, but more frequently between the ninth and twelfth days, and always before the development of the exanthem. Occasionally the prodromal angina of measles concurs with pseudo-appendicitis. The tonsils as well as the appendix contain many giant cells. The vascular endothelium likewise may form giant cells and as a result, small blood vessels may become obliterated and there may be an extravasation of blood pigment. The author thinks that this explains the chocolate color of the prodromal angina of measles to which attention had been called by Veilchenblau. He considers the prodromal angina of measles the expression of an allergic reaction that involves the entire lymphatic system of the oral cavity and is more or less analogous to the accompanying anginas of vaccination, of serum disease of idiopathic glandular fever of leukemia, of agranulocytosis, of many septic infections and of other infectious diseases. The author shows that the prodromal angina of measles is a misleading symptom rather than a leading symptom in the early diagnosis of measles. Only an exact knowledge of the prodromal angina of measles may make it valuable for the diagnosis of measles.

Periodic Vomiting During Childhood—Sive shows that in the periodically recurring attacks of vomiting with acetoneuria there exists a hepatic dysfunction with increased elimination of the products of metabolism among them ketone bodies. This disturbance which resembles that in carbohydrate deficiency or in an excessive one-sided fat diet cannot be due to a glycogen deficiency, for epinephrine mobilizes a normal quantity of sugar in the blood. During the attacks of vomiting the blood sugar is not necessarily reduced and in the cases observed by the author it is not below the values that are found in healthy children (particularly in nervous ones) after fasting. The vomiting shows no regular and direct relation with the values of the blood sugar or the acid elimination. Administration of epinephrine as well as of sugar always exerts a favorable influence on the general condition, and in some cases the predisposition to vomiting is likewise reduced by medication with epinephrine. The administration of sugar is always facilitated by the epinephrine medication and, if sugar is given repeatedly after suitable intervals it may have a curative effect. During the attack-free intervals a ketogenic diet reveals no disturbance in the hepatic function, but in two out of nine cases it was possible to produce typical attacks with such a diet. The liver reacts normally also to sugar tolerance tests during the symptom-free interval. It is significant for the clinical course that attacks nearly always are preceded by premonitory symptoms. The attention of the parents and of the patients should be called to these signs for, if sugar is given early enough the attacks of vomiting can be prevented. The fact that children with acetoneuric vomiting frequently have an aversion to sweets and show a preference for fatty foods is of especial interest.

*Sclerodema Adultorum (Buschke). G. A. Björkenheim—p. 134

*Osteitis Deformans Paget. Case. B. von Bonsdorff—p. 147

Treatment of Abscesses of Brain—Wolff reports a case of abscess in the frontal lobe operated on according to Lemaitre. The patient recovered. With regard to diagnosis, attention is called to the difference of twenty beats per minute in the pulse in reclining and sitting positions, a phenomenon first mentioned by Goldstein and established by Kaila in disturbances of the circulation of the spinal fluid of acute onset.

Sclerodema Adultorum (Buschke)—Björkenheim reports a case believed to be the first seen in Finland, in a woman aged 34, observed by him both before and during the disorder and closely examined two years later after complete recovery. The clinical picture agrees with the typical symptoms of this disorder as described in the literature. After one and one half years the patient was practically without symptoms. The typical marked lymphocytosis has completely disappeared. An endocrine disturbance seemed probable. Thyroid therapy was without definite effect.

Osteitis Deformans Paget—In von Bonsdorff's instance in a woman, now aged 59, the symptoms of avitaminosis and signs of endocrine disorder were so marked that an etiologic significance is ascribed to them.

Sarcoid of Boeck Treated with Agent for Leprosy (Antileprol). Twelve Cases. S. Lomholt—p. 187

*Infantile Scurvy Treated with Ascorbic Acid. Elisabeth Svendsgaard—p. 209

Sarcoid of Boeck Treated with Agent for Leprosy—Lomholt asserts that in the twelve cases of typical sarcoid of Boeck treatment with chaulmoogra oil was followed in eight cases by disappearance of the specific infiltrations in the skin and in four by improvement. Lymphomas present also disappeared and lesions of the mucous membrane of the nose and mouth cavity were influenced favorably. As a rule, daily intravenous injections of 15 cc of chaulmoogra oil was given and was on the whole well borne. Intramuscular injections in the buttocks seemed to act even better than the intravenous injections but often caused pain and in one case abscess formation. A similar effect of the chaulmoogra oil was seen in other cases of granulation tissue with tuberculoid structure, as in granuloma annulare but far less marked in tuberculous lymphomas. In almost all the patients the injections produced an eosinophilia sometimes marked which developed slowly but disappeared rapidly. The regularity and nature of the clinical effect of the agent the author says, call for continued systematic investigations.

Infantile Scurvy Treated with Ascorbic Acid—In the two cases of marked scurvy reported by Svendsgaard, recovery occurred in a few days, with a diet absolutely deficient in vitamin C on treatment with ascorbic acid in a dosage of 30 mg daily by mouth.

Report in Hospitalstudende 1933 p. 835). Case. E. Husted—p. 226

Modern Wheat Milling and Possibility and Desirability of Improvement of Wheat Flour from Nutritive Point of View. P. Vogt Müller—p. 227

Spontaneous Recovery in Pernicious Anemia?—Lassen reports a case believed to be true pernicious anemia in a woman, aged 61 with spontaneous remission for fully nine years. The patient has never had liver or liver preparations. On recent examination a positive congo red reaction was found after injection of histamine, on four repeated later examinations the congo red reaction was negative and the maximum total acidity was 10. Since there is a slight megalocytosis and the patient has acroparesthesia the author thinks that she has had and has a 'pernicious anemia with anemia.' There are no other symptoms attributable to an anemic myelopathy.

Recurring, Histologically Benign Tumor of Breast—Husted now reports the transition into a sarcoma of this tumor, originally an intracanalicular fibroadenoma of typical appearance. The patient died from extensive metastases.

CIRCULATORY STASIS OF INTRAPERICARDIAL ORIGIN

THE CLINICAL AND SURGICAL ASPECTS OF THE
PICK SYNDROME

CLAUDE S. BECK, M.D.

AND

E. H. CUSHING, M.D.

CLEVELAND

In referring to the various disorders of the pericardium, one is accustomed to use such terms as pericarditis with effusion, adhesive pericarditis, callous pericarditis, purulent pericarditis, hydropericardium, hemopericardium and pneumopericardium. These anatomic conditions, diversified as they are, have a common physiologic relationship. They produce two closely related clinical syndromes. These are the syndromes of acute and chronic intrapericardial pressure. It is our purpose to describe these clinical syndromes and recommend the adoption of this physiologic concept. We believe this would aid in the diagnosis of pericardial lesions in much the same way as the physiologic conception of intracranial disorders has aided in the diagnosis of intracranial lesions. The syndromes of acute and chronic intracranial pressure are well understood and their physiologic aspects have been of great importance in furnishing the guide to specific anatomic diagnoses. For example, a patient who is unconscious, with Cheyne-Stokes respiration, a high blood pressure, a slow pulse rate, and possibly choked disks, has acute intracranial pressure, while a patient who is toxic, weak and drowsy, with choked disks, has chronic intracranial pressure. It requires further data to determine whether the first patient has an intracranial infection, tumor or hemorrhage, and whether the second patient has a space-occupying tumor, a block of the cerebrospinal fluid system, an infection or a slow hemorrhage. The correct lead to the diagnosis lies first in the recognition of the pressure syndrome. The diagnosis of pericardial lesions is frequently overlooked. If the syndromes of acute and chronic intrapericardial pressure were generally recognized we believe that the specific anatomic diagnosis would be made more frequently.

THE SYNDROMES OF ACUTE AND OF CHRONIC INTRAPERICARDIAL PRESSURE

In order to understand the mechanism producing these clinical conditions, it is advisable to refer to certain pressure relationships that exist within the chest. Under normal conditions of respiration the pressure

within the pleural cavity is always negative (by about 8 or 10 cm. of water). This negative pressure originates from the elastic recoil of the lungs. It is transmitted to all the intrathoracic viscera. The mediastinal space and the intrapericardial space, being bounded by soft, nonrigid walls, likewise carry a negative pressure. The pressure in the venae cavae and right auricle is negative by about 3 or 4 cm. of water. Under normal conditions the blood meets no obstruction at the point where the venae cavae pass through the pericardium. Under certain abnormal conditions the pressure on the heart and the short segments of venae cavae that lie within the pericardial cavity is increased. This mechanism can easily strangle the circulation and can bring it to a partial or complete standstill. When the intrapericardial pressure increases suddenly, the circulation is immediately stopped and the blood collects in the venous reservoirs. In a few moments these reservoirs are filled and the pressure that is built up may become great enough to break through the pericardial barrier. In this event the circulation starts up again. The amount of blood entering the heart may be greatly cut down, but the vasomotor center is so efficient that, with only 50 per cent of the normal amount of blood entering the heart, the arterial pressure may show little if any reduction.¹ If the venous reservoirs cannot build up sufficient pressure to break through the pericardial barrier, the circulation comes to a complete standstill. In other words, it is incompatible with life for the pressure within the pericardium to exceed the pressure in the venae cavae.

The most common barrier is produced by fluid. The fluid may be an exudate or a transudate; it may be sterile or infected; it may be bloodstained or whole blood. The heart may be compressed also by a tight envelop of scar tissue or by a deposit of calcium; it may be pressed on by a neoplasm or by a collection of gas in the pericardial cavity. The gas may consist of air or it may be produced by gas-forming bacteria.

Acute intrapericardial pressure is usually caused by hemorrhage from wounds of the heart or coronary vessels or from rupture of a weakened myocardium, or from an aneurysm. It is sometimes seen with a rapidly progressing suppurative infection. The clinical picture is exactly what one would expect from an acute strangulation of the heart. The veins are full of blood. Their walls have not been stretched by chronic pressure and they are not prominent, but the venous pressure is elevated by as much as 15 cm. of water. There has not been sufficient time for ascites, hydrothorax or edema to develop. On the arterial side of the circulation the vasomotor center is doing what it can to maintain an

CIRCULATORY STASIS—BECK AND CUSHING

JOUR. A. N. A.
MAY 12 1924

adequate pressure.² As the arterial circulation fails, the body cools and the skin becomes moist, cold and pale. The patient at first may go through a period of excitement and anxiety but, as the brain becomes anemic consciousness is lost. Examination of the precordium shows little. The cardiac sounds are faint and distant or may be inaudible. There is no pulsation of the precordium. The area of cardiopericardial dullness shows little or no perceptible increase. It is unnecessary and may be unwise to spend the time taking a roentgenogram if urgent surgical treatment is to be carried out.

If the strangulation of the circulation takes place more slowly and does not become complete, the clinical picture of chronic intrapericardial pressure develops. In the chronic condition a considerably greater pressure can be tolerated than in the acute condition. A high venous pressure is built up as a protection and this pressure may be as high as 30 to 34 cm of physiologic solution of sodium chloride. The veins dilate in response to the prolonged pressure and they sometimes stand out like goose quills.

If the intrapericardial barrier is fluid, the pericardium dilates gradually and may contain as much as several liters of fluid. The liver and spleen enlarge. Ascites and hydrothorax develop. Subcutaneous edema may occur, but this is not marked and appears later.

Cyanosis, weakness, and dyspnea on exertion are present. The arterial and pulse pressures are reduced. The systolic pressure may be about 90 to 100 mm of mercury and the diastolic pressure about 70 to 80 mm of mercury. Pulsus paradoxus is present. The minute volume output of the heart is reduced. The vital capacity is reduced. The response to exercise shows a delayed return of pulse and arterial pressures to former levels. The electrocardiogram shows low voltage and shunting of the QRS complex in all leads from clinical examination of the precordium and from the roentgen examination depend on the pathologic process that is present. As already stated, this may be due to fluid or scar or to a combination of fluid and scar (fig 2). If fluid is present, the precordial shadow is increased, the contour of the cardiopericardial shadow changes as the patient is moved from the erect to the recumbent position, and the amplitude of cardiac pulsation is reduced. If scar is present, the size of the cardiopericardial shadow may be approximately normal,

it may be larger or smaller than normal, there may be fixation to the sternum, the pulsation may be reduced or absent and the venae cavae are distended. A pericardial paracentesis may yield additional evidence as to the presence of pericardial scar, calcification or fluid. If scar is present, the needle will encounter firm resistance when the pericardium is reached and if inserted into the scar, will be dragged back and forth with each cardiac cycle. The scar may be so tough that it is impossible to penetrate it with the needle.

The clinical picture of chronic intrapericardial pressure was described by Friedel Pick³ in 1896. He deserves credit for diverting attention from the liver to the pericardium as the primary seat of the trouble, but it is doubtful whether the continued use of the term "Pick's disease" is advisable in referring to this group of diversified conditions. It is more informative to refer to the mechanism producing the condition as, for example, the syndrome of chronic intrapericardial pressure produced by scar tissue, of chronic intrapericardial pressure produced by a tuberculous effusion, of chronic intrapericardial pressure produced by a sterile effusion or of acute intrapericardial pressure produced by a ruptured aneurysm.

This syndrome of chronic intrapericardial pressure is a type of circulatory failure that frequently can be cured by operation. It is important that this type of circulatory decompensation be diagnosed correctly so that operative treatment can be carried out in appropriate cases. Although its occurrence is rare when compared to that of excessive large group of patients suffering from cardiac failure nevertheless there are probably in this country several hundred cases of chronic intrapericardial pressure. The vast majority of these are not recognized and accordingly they are denied proper treatment. The operation for the relief of chronic pressure is a task with which the surgeon may be relatively unfamiliar. Few operators acquire experience in operating on the heart. Unlike any other organ in the body, the heart is in constant motion, and the surgeon must establish a new set of reflexes for this

Fig 2—Various anatomical conditions that produce chronic intrapericardial pressure. Each of these conditions can produce the so-called Pick syndrome.

operation. This syndrome has been produced experimentally by the introduction of surgical solution of chlorinated soda into the pericardial cavity.⁴ The laboratory

² By common usage the term blood pressure seems to mean arterial pressure. In the syndromes of intrapericardial pressure the venous pressure is of relatively greater importance than the arterial pressure. We prefer to make venous pressure determinations by the direct method (fig 1).

ratory offers an invaluable opportunity to acquire experience in performing this operation

It is not our purpose in this paper to trace the successive steps that have been taken in the development of the surgical treatment and the results obtained. Suffice it to say that patients who have been bedridden have been restored to active life, that in a few cases the circulatory relief has been complete and apparently permanent, and that in the future with improved methods and experience the operation undoubtedly will lose much of its hazard

REPORT OF CASES

The following nine cases of chronic intrapericardial pressure are presented to show the similarity of the clinical pictures produced by dissimilar pathologic processes. Six of these patients were operated on

CASE 1—A boy, aged 13 years, complained of weakness, shortness of breath and pain in the upper part of the abdomen. These symptoms had been present for about one and one-half years, they had been insidious in onset and were becoming more marked. Several transient attacks of jaundice and epigastric pain without fever appeared during this period. There was no history of acute rheumatic fever, chorea or pneumonia. He had had frequent attacks of sore throat, and his tonsils had been removed eight years before.

The patient was bedridden, orthopneic, cyanotic and extremely weak. Ascites was marked. The liver and spleen were large and firm. Clinically there was no hydrothorax. Serotal edema was present, but there was no other subcutaneous edema. Arterial pressure was 90 mm of mercury systolic and 70 mm of mercury diastolic. The pulse pressure was 20 mm of mercury. The venous pressure was 35 cm of physiologic solution of sodium chloride. The vital capacity was 1,500 cc (calculated capacity 2,700 cc). Pulsus paradoxus was present. Electrocardiograms showed low voltage and slurring of the QRS complex in all leads. The T waves were iso electric in the first and second leads and inverted in the third lead. There was no shift of electrical axis with change of position. There were no cardiac murmurs. Fluoroscopic examination showed the amplitude of pulsation in each ventricle to be almost completely obliterated and the heart to be fixed in position.

Pericardiectomy was carried out Nov. 21, 1929. The parietal pericardium and epicardium were everywhere adherent. These structures were transformed into a layer of scar tissue several millimeters in thickness (fig. 2A). This scar was dissected from the heart. Under the microscope it showed only dense fibrous connective tissue without any evidence of tuberculous or rheumatic infection. There was dramatic improvement in the circulation as soon as the heart was liberated.

The patient has led an active life since operation without showing the slightest evidence of circulatory failure. March 15, 1934 there was no ascites, the liver and spleen were not palpable, there was no hydrothorax and no serotal edema. The arterial pressure was 120 mm of mercury systolic and 70 mm of mercury diastolic, the pulse pressure was 50 mm of mercury, the venous pressure was 4 cm of physiologic solution of sodium chloride, the vital capacity was 3,500 cc (normal). Pulsus paradoxus was absent. The electrocardiogram showed slight slurring of the QRS complex in the first lead, none in the other leads and marked increase in voltage. The T wave

was upright in the first lead and inverted in the second and third leads. There were no cardiac murmurs and the fluoroscopic examination showed normal pulsation in each of the cardiac chambers. Dr. David Steel said that under the fluoroscope one would not suspect that the heart had ever been pathological. A cardiac output determination by means of the acetylene method⁶ showed the following: pulse rate per minute 72, oxygen consumption 236 cc per minute, arterio-venous oxygen difference 57.3 cc per liter, cardiac output per minute, 4.11 liters, cardiac index, 2.4, stroke output of heart 57 cc. The result of this determination was in agreement with other determinations and showed the minute volume output and the stroke output of the heart to be normal. The operation was carried out four years ago, and the patient now shows no evidence of any circulatory abnormality, whereas before operation he was bedridden.

CASE 2—A man, aged 30, referred by Dr. H. N. Kenwell of Buffalo, was admitted to the Buffalo City Hospital April 1, 1931. Weakness and swelling of the abdomen had developed one month before admission. The examination showed a marked degree of ascites, slight edema of the serotum, eyelids and ankles, marked engorgement of the veins, cyanosis and dyspnea. He had a troublesome cough, some pulmonary edema and hydrothorax. He had no fever. The arterial pressure was 110 mm of mercury systolic and 90 mm of mercury diastolic. The pulse rate ranged from 90 to 100 per minute. The venous pressure was 35 cm of physiologic solution of sodium chloride. (This and subsequent determinations of the venous pressure on this patient were not corrected for capillarity. Glass tubing with a rather small bore was used and the readings may be as much as 4 cm too high.) Pulsus paradoxus was present. The heart and pericardium were larger than normal and a change in the contour was determined by fluoroscopic examination when the patient was changed from the erect to the reclining position. This indicated fluid in the pericardial cavity. The cardiac sounds were faint, there were no murmurs. The margin of the liver was four fingerbreadths below the costal margin. Tubercle bacilli could not be found in the sputum, the ascitic fluid or the intrapleural fluid when injected into a guinea pig. The electrocardiogram showed slurring of the QRS complex, notching of the P wave in lead I and inversion of the T wave in lead III.

He remained in the hospital continuously without showing any febrile response. The abdomen was tapped repeatedly. August 8 operation was carried out. An H-shaped incision was made over the precordium so that a bilateral exposure of the heart could be obtained. The third, fourth, fifth and sixth costal cartilages were removed on the left side. The parietal pericardium consisted of thick, tough scar tissue about 3 mm in thickness. The pericardial cavity contained 200 cc of bloody fluid. There were no intrapericardial adhesions. The heart, especially over the base, was covered by a layer of scar tissue measuring about 1 mm in thickness; this scar disappeared over the apex. The parietal pericardium was excised as widely as possible. The fluid was removed and an attempt was made to excise the epicardial scar. This was difficult to do because it required sharp dissection and repeatedly the dissection went into the myocardium. Four pieces were removed, each of which measured about 2 cm in each direction. The areas from which the scar had been removed were connected by linear incisions and the margin of the scar was undercut. After this was done the heart became larger and it was apparent that the restricting effect of the epicardial scar was reduced. The mechanism producing this clinical syndrome consisted of a thickened parietal pericardial scar that could not stretch, fluid in the pericardial cavity that pressed on the heart and venae cavae and an epicardial scar that compressed the heart and limited the diastolic excursion (fig. 2E). A drain was placed in the wound.

The circulation was definitely improved during and after operation. The cyanosis at times was completely absent. Arterial pressure was 100 mm of mercury systolic, 70 mm of mercury diastolic. The pulse pressure was increased. Pulsus

⁶ We are indebted to Miss Alice J. Mahly for the cardiac output determinations.

palpable 11 cm below the costal margin. The spleen was not felt. There was no edema of the lower extremities. Roentgenologic examination showed an enlargement of the cardiac outline typical of pericardial effusion (fig 5). The pulsations were practically absent. The lung fields showed shadows characteristic of pulmonary tuberculosis. There were also shadows due to calcification in the region of the cervical lymph glands. Electrocardiograms showed slight right axis deviation, low voltage and slurring of the QRS complex in all leads. The venous pressure was 25 cm of physiologic solution of sodium chloride. The vital capacity was 50 per cent of normal. Cardiac output studies showed an output of 151 liters per minute. This was a decrease of 49.5 per cent of normal. Before fluid was aspirated from the pericardial cavity the intrapericardial pressure was 21 cm of water, and following removal of 250 cc of serosanguineous fluid the pressure fell to zero. Guinea-pigs were inoculated with this fluid but no evidence of tuberculosis was found. Abdominal paracentesis was also performed. Fluid reaccumulated rapidly in both abdominal and pericardial cavities. Sputum examination revealed tubercle bacilli. The patient presented evidence of circulatory stasis due to pericardial effusion (fig 2C). The effusion was most probably of tuberculous origin, and operative intervention was contraindicated with the coexisting active pulmonary lesions.

CASE 8—An intelligent man, aged 28, a teacher, referred by Dr W J Leahy of Mannington, W Va, had had ascites for eight years. He had had no illness preceding the onset of these symptoms. The abdominal swelling started insidiously and three exploratory laparotomies were performed. Ascitic fluid was injected into guinea-pigs and no evidence of tuberculosis was found. Except for nine months in 1929 the patient had had abdominal paracentesis every three weeks, and it was estimated that 780 liters of fluid had been removed. There was some weakness and dyspnea, but the patient occasionally played baseball and was able to complete, with honors, the work required for a college degree. A roentgenogram taken a year before admission to the Lakeside Hospital showed calcified deposits in the pericardium.

He was emaciated and slightly cyanotic and had a prominent abdomen. He weighed 170 pounds (77.1 Kg). There was

Fig 5 (case 7)—Pericardial effusion. The patient had active pulmonary tuberculosis.

Slight pitting edema was present in the lower extremities. The vital capacity was 52 per cent of the estimated normal. The venous pressure was 27 cm of physiologic solution of sodium chloride. Cardiac output studies showed an output of 211 liters per minute. This was 50.4 per cent below normal.

Fluoroscopic examination of the heart showed the pulsations to be barely visible. The heart was entirely encased in a capsule of calcium (fig 6). There was fluid in the left pleural

cavity. Electrocardiograms showed slight right axis deviation with slurring of the QRS complex in all leads and very low voltage. The electrical axis was almost fixed.

Pericardiectomy was performed, July 31, 1933. The pericardium was calcified. The calcium deposits extended over both ventricles, anteriorly and posteriorly (fig 2A) and surrounded the pulmonary artery like a ring. The pericardium was dissected from the anterior and lateral aspects of the heart. The calcium band about the pulmonary artery was removed with a rongeur. Histologic examination revealed densely fibrous and hyalinized connective tissue with many areas of calcium deposit. The heart dilated following the removal of the adherent pericardium and the arterial pressure was 115 mm of mercury systolic and 78 mm of mercury diastolic when the patient left the operating room.

He responded extremely well to the operative procedure, and three weeks after the first operation the hydrocele was repaired under local anesthesia. Cyanosis disappeared. The pulse pressure was increased. The arterial pressure became normal. The venous pressure fell to 12 cm of physiologic solution of sodium chloride but several weeks later rose almost to the preoperative level. Marked diuresis took place and the patient was discharged from the hospital eight weeks after pericardiectomy.

A report that was sent by the patient, dated November 12, says: "I feel better than I have for years. It seems that I have more energy in the last few days than I ever have had. My heart seems to beat well and the pulse is much stronger. My weight is 158 pounds [71.7 Kg]." As recently as April 1, 1934, the patient stated: "I feel excellent and have much energy. My color is better than it has been for ten years. The strength of the pulse is very much improved."

CASE 9—A man, aged 24, referred by Dr Roy W Scott of Cleveland, with the diagnosis of pericardial scar, presented a typical picture of chronic intrapericardial pressure due to scar tissue compressing the heart. The etiology was obscure. Tuberculosis was suspected but was not proved. The patient had become a chronic invalid and accepted the possibility of cure by operation. The operation was carried out April 7, 1934. The heart was compressed by a thickened adherent pericardium. The pericardial scar was dissected from the heart and a wide resection was carried out. After the pericardial scar was incised and dissected free from the heart, the circulation was improved. The heart enlarged and the heart beat was more forceful. At the present moment four days after operation, the patient is in good condition and the circulation shows improvement.

SUMMARY

1 The various anatomic disorders of the pericardium have a common physiologic relationship. Lesions of the pericardium produce the syndrome of either acute intrapericardial pressure or chronic intrapericardial pressure. We recommend the use of this conception of pericardial disorders.

2 The surgical aspects of chronic intrapericardial pressure have been presented. Operation was carried out in six of the nine cases reported.

AN IMPROVED TEST FOR OCCULT
BLOOD, ESPECIALLY IN
THE URINE

WILLARD J STONE, M D

AND

GEORGE T BURKE, M D

PASADENA, CALIF

Orthotolidine¹ was first proposed by E B Phelps² in 1909 as a qualitative test for minute amounts of free chlorine or hypochlorites in water. It is a crystalline basic body of the aromatic series obtained by reduction from orthotoluidine. It has a melting point of 129-130 centigrade and is quite insoluble in distilled water. It is quite soluble in acid solutions and in alcohol and ether. Rutten and Hardisty³ in 1912 described the use of orthotolidine as a test for the detection of blood. They used a 4 per cent solution in glacial acetic acid and added a small amount of perhydrol (Merck) as an oxidizing agent to obtain a blue color in the presence of blood. They stated that the solution would detect hemoglobin in a dilution of one part in 7,000,000 parts of water in a dilution of one part in 24,000 parts of urine, in a dilution of one part in 100,000 parts of fecal material, and of one part in 30,000 parts of stomach contents.

In the course of a search for a new hemoglobin color standard, we have found orthotolidine useful in the detection of minute quantities of blood in urinary sediments. It is safe to say that the average laboratory urine report made by technicians rarely mentions the presence of red cells unless the presence of blood is grossly evident. Red blood cells in the sediment are often crenated or disintegrated in urine specimens a few hours old and are confused with leukocytes. The formed elements including red cells, are frequently disintegrated in alkaline urine. The continued presence of red blood cells in urinary sediments has important clinical significance in that it may attract attention to glomerular inflammatory changes which are frequently overlooked in the absence of albuminuria or other gross evidences of disturbance. Such observations have especial significance in latent stages of chronic hemorrhagic Bright's disease (glomerulonephritis). We have found frequently that red cells were excreted more or less constantly in patients with evident foci of infection. Such observations have important clinical implications of glomerular inflammation. The presence of a few red cells, leukocytes or casts, in the absence of other symptoms may have little significance following unusual exercise or exertion.

Addis⁴ examined a series of healthy students and found, by counting the red cells in the urine that for twelve-hour night periods the number averaged 65,000 cells. The individual highest count obtained was 425,000 red cells for a twelve-hour period. This would mean for an average twelve-hour night excretion of about 400 cc of urine that the number of red cells varied approximately between 150 and 1,000 per cubic centimeter. The persistent excretion of 1,000 red cells per cubic centimeter of urine in our experience would

not be considered within the limits of normal variation and would point toward some source of chronic glomerular irritation. The important point is that such numbers are not recoverable easily by centrifugation, since disintegration or solution frequently has occurred.

Our experiments show apparently that from 50 to 80 per cent of red cells are recoverable. This point need not be considered as settled, since varying degrees of alkalinity and preservation of specimens, as well as the rate of centrifugation may influence the result. We have considered that 50 per cent of the cells were recoverable as being a useful average in clinical work. The following experiment will illustrate the point.

To 15 cc of normal, neutral or slightly acid urine, which had been filtered twice and which contained no microscopic evidence of blood, 75,000 red cells were added. The concentration then was 5,000 cells per cubic centimeter of urine. The 15 cc quantity was centrifuged at 1,500 revolutions per minute for five minutes. The amount of sediment obtained was about 0.1 cc or 100 cmm, from which a count was made of the red cells. The count showed that the sediment contained 400 red cells per cubic millimeter. This would be equal to 40,000 red cells in approximately 0.1 cc of sediment representing 15 cc of urine. In other words, about 40,000 cells were recovered of the 75,000 cells originally present. Approximately then 50 per cent plus were recoverable by centrifugation at 1,500 revolutions per minute for five minutes. This may be expressed in formula as follows:

$$\frac{\text{Number of red cells per cmm} \times \text{millimeters of sediment} \times 2}{\text{Number of cc of urine used}}$$

For example 15 cc of urine placed in a 15 cc graduated centrifuge tube yielded 0.1 cc of sediment with 400 red cells per cubic millimeter. The estimation would be as follows:

$$\frac{400 \times 100 \times 2}{15} \text{ or } 5,333 \text{ red cells per cubic centimeter of urine}$$

The labor entailed in counting the red cells in urinary sediments restricts its usefulness in clinical work. We have found the following procedure useful:

1 Orthotolidine 1 per cent in chemically pure methyl alcohol (It dissolves with slight difficulty and keeps at least ten months.)

2 Glacial acetic acid one part and commercial hydrogen peroxide two parts. (This keeps for three or four months, probably longer.)

3 Fifteen cc of urine is centrifuged at about 1,500 revolutions per minute for five minutes. The supernatant fluid is poured off. A portion of the sediment is prepared for microscopic examination in the usual way. To the remaining sediment two drops of the orthotolidine solution is added plus two or three drops of the acid-peroxide solution. In the presence of blood cells aggregating 100 per cubic millimeter of sediment (approximately 1,350 per cubic centimeter of urine) a greenish blue color develops lasting about one minute. In the presence of from 300 to 500 red cells per cubic millimeter of sediment (approximately 4,000 to 6,500 cells per cubic centimeter of urine) a deeper blue color develops lasting about one minute. In the presence of larger numbers of red cells, aggregating 1,000 per cubic millimeter of sediment (approximately 13,000 per cubic centimeter of urine) as in hemorrhagic Bright's disease (glomerulonephritis) a deep blue color develops lasting two minutes or longer.

Undiluted blood serum 10 per cent sodium hydroxide strong trisodium phosphate solutions and probably other strong alkalis will give positive reactions. Pus cells or any of the common organic or inorganic constituents found in the urine do not give positive reactions.

5 In two recently observed cases of chronic cyanosis not of pulmonary or cardiac origin and without the presence of blood cells or hemoglobin in the urine delayed atypical reactions occurred. In both of these patients the urine gave a greenish color with orthotolidine and the acid peroxide mixture which developed slowly and did not fade for several hours. The significance of the reaction in chronic cyanosis is being studied further.

¹ Orthotolidine can be obtained from the Ketchikan Laboratory, Eastman Kodak Company, Rochester, N. Y. in quantities of 25 Gm at a cost of 75 cents.

² Phelps, E. B. quoted by Thierault, E. J. The Orthotolidine Reagent for Free Chlorine in Water. *J. Hyg. Health Rep.* 42: 668 (Jan. 22) 1922.

³ Rutten, R. F. and Hardisty, R. H. M. *Canad. M. A. J.* 2: 99 1912.

⁴ Addis, Thomas and Oliver, Jean. The Renal Lesion in Bright's Disease. New York: Paul B. Hoeber, Inc. 1931.

CONCLUSIONS

1 A 1 per cent solution of orthotolidine in chemically pure methyl alcohol and a mixture of one part of glacial acetic acid and two parts of commercial hydrogen peroxide are useful for an approximate quantitative determination of the number of red blood cells in the urine. These solutions are cheap and stable.

2 In a relatively large series of examinations of specimens of urine examined within six hours after voiding, no positive reaction has been obtained except when microscopic blood was present.

3 Specimens of urine containing as high as 5,000 red cells per cubic centimeter will in most instances be undetected by the usual microscopic examinations, since such numbers may represent only one or two cells per high power field.

AMEBIC ABSCESS OF THE LIVER

REPORT OF CASES WITHOUT PREVIOUS MANIFESTATIONS OF AMEBIASIS

HUGO A. FREUND, M.D.

DETROIT

The recent outbreak of amebic dysentery and the spread of infested persons throughout the country has awakened a lively interest in the disease and its sequelae. Diarrheas of every type are now viewed with suspicion. Many laboratories have been called on to do routine cultures of feces for amebas. It is of importance that attention be given to every person who has sojourned in known infested areas or has been exposed to possible carriers, even if that individual has not manifested any evidence of intestinal disturbance. Latent infections are well recognized by the profession and their danger to the host as well as the community is self-evident. Craig¹ has pointed out that diarrhea may never occur during the course of the infection. Rogers² in several articles emphasized this fact.

For the past few months, sequelae of amebic dysentery of serious types and definite importance have been developing among individuals who are widely scattered throughout the country. These patients, while carrying a latent infection, have been insidiously developing secondary complications, chief among which is abscess of the liver. This condition is a common complication of recognized amebic dysentery. It is generally accepted that it follows in about 20 per cent of cases, yet it is rarely known to appear without the previous knowledge of a recognized focus or without preexisting intestinal symptoms. The time of appearance of the hepatic abscess after the primary infestation of the patient with amebas varies widely. In acute amebiasis, areas of toxic necrosis of the liver parenchyma are frequently encountered at autopsy, and definite abscess formation has been reported as early as three weeks after the onset of the disease. On the other hand, liver abscess in chronic amebic dysentery may not appear for years. Merklen, Waltz, Albot and Kabaker³ recently discussed a case of chronic amebiasis in which recurrent

attacks of hepatitis with icterus occurred over a period of eleven years and at operation a chronic thick-walled abscess was evacuated.

During the past six months there has been a marked increase in the incidence of abscess of the liver in Harper Hospital. Eight cases have been diagnosed and operation performed at this writing since Oct 1, 1933. In the preceding five years only seventeen cases were recorded.

For comparison, attention is directed to a recent article by Gesner,⁴ who analyzed 100 cases of liver abscess that came under observation in the New Orleans Charity Hospital from 1916 to 1932. Of these, fifty-seven were amebic abscesses, a finding that might be expected in that region. On the other hand, Collins,⁵ in reviewing 18,300 autopsies in Minneapolis, reported only eleven cases in which liver abscess was the cause of death and stated that appendicitis and perihepatic inflammatory conditions were found to be the precursors of the abscesses.

Of the eight cases that have been studied, four were proved to be of amebic origin, two were characteristic of amebic liver abscess though the parasite was not found, and two were definitely not of amebic origin. Of the four proved cases, three failed to present any history of previous gastro-intestinal symptoms. Though each of these three cases could be traced to a definite source of contagion, it was impossible to elicit from the patient any history of symptoms of diarrhea, watery or bloody defecations, cramps or tenesmus. It seems of importance, therefore, that record be made of these three cases, which, following an indefinite latent period, have suddenly presented the symptoms and signs of liver abscess.

REPORT OF CASES

CASE 1.—F. P., a man, aged 45, white, a librarian, complained of a feeling of fatigue and lassitude, Feb 2, 1934. His appetite became poor and pain developed in the upper right quadrant. This was described as a feeling of soreness, extending over the margin of the ribs and radiating to his right shoulder. Turning from side to side aggravated the pain. February 3 he had a chill lasting fifteen minutes, the temperature rising to 101 F. The following day he had two chills of shorter duration. The malaise increased and the distress became localized in the region of the ninth and tenth ribs on the right side. There was no nausea nor vomiting, nor were there any intestinal complaints. He was not jaundiced. On physical examination the abdomen was moderately distended, the margin of the liver extended two finger breadths below the costal margin, the lung liver dullness was in the fourth interspace. Sharp direct percussion over the ribs elicited severe pain. The right thorax was somewhat hyperresonant. No rales were heard. The cardiovascular system was normal. The spleen was not palpable. The icteric index was 12. The van den Bergh test was slightly positive in the direct and positive in the indirect. The Wassermann reaction was negative. A flat plate revealed an enlarged liver with slight bulging of the convexity of the right leaf of the diaphragm. The costophrenic sinus was clear. The stools were negative for amebas and cysts. The blood count was: hemoglobin 85 per cent, red blood cells 4,480,000, white blood cells 23,500, polymorphonuclears 85 per cent, of which 68 per cent were unsegmented and 17 per cent segmented. The urine was normal. Operation was performed by Dr. Brooks, who made a gallbladder incision and on examining the colon found marked cecal inflammation. The appendix was very long, edematous and red. The gallbladder showed moderate distention, no stones were palpated and there were no adhesions. The stomach, duodenum and remainder of the colon were apparently normal. The spleen was slightly

5 Collins A. N. Liver Abscess. Minn. otol. Med. 15: 756-762 (Nov.) 1932.

enlarged, very firm, and surrounded by adhesions. The liver was about twice the normal size. The right lobe extended 3 inches below the umbilicus. In the right lobe well up toward the diaphragm, about 2 inches from the superior border, a softened area was found covered with thin exudate. Definite liver abscess was palpated. The appendix was removed. An aspirating needle was placed in the abscessed area and 15 cc of thick, greenish red pus was removed. A stab drain was inserted just below the lower border of the last rib for drainage of the abscess. The cavity was opened and about 1 quart of pus escaped. The pus was immediately examined but no amebas were found. Culture revealed *Staphylococcus aureus*. Cultures did not reveal amebas. Pathologic examination of the appendix revealed active chronic inflammation of the appendiceal mucosa with many plasma cells and eosinophils. Amebas were found in the lumen and wall of the appendix.

Convalescence has been uneventful. Subsequently amebas were found in the stool.

CASE 2—M. C., a woman, aged 19 years, white, a student, experienced a sudden, severe pain in the upper abdomen localized in the epigastrium, Feb. 18, 1934. It was relieved by lying still but aggravated by movement. There was no nausea or vomiting. The pain subsided somewhat during the night so that on the following day she attended school but she was forced to return home at noon to rest. During the next four days the pain remained stationary and she was about in her room. She did not consult a physician. February 28, the pain became more severe, radiating along the margin of the ribs on each side. The bowel movements were normal, formed, and occurred twice daily. The patient was admitted to the Harper Hospital, March 2, acutely ill. The temperature was 103, the pulse 120. At the time of examination she was lying on her right side suffering intensely from pain when she attempted to lie in a dorsal position. A well defined mass was felt high in the epigastrium, apparently connected with the liver. It was sharply circumscribed and exquisitely tender. The remainder of the abdomen was soft and pliable. The spleen was not felt. The lung liver dullness was not elevated. The lung fields and cardiovascular system were normal. Blood count revealed hemoglobin 77 per cent, red blood cells, 4,020,000, white blood cells 27,400, polymorphonuclears, 88 per cent, of which the segmented were 61 per cent and the non-segmented 27 per cent. The Wassermann reaction was negative. The icteric index was 4. The van den Bergh test was negative in direct and indirect. The urine was normal. A few fecal masses obtained with a colon tube were negative for amebas and for cysts.

Dr. MacAlpine made a midline incision from the ensiform cartilage to the umbilicus. The omentum was adherent to the anterior abdominal wall, just below the liver margin. When the adhesions were freed the right lobe of the liver was exposed, enormously engorged, dark red and somewhat mottled. A fluctuating area appeared 3 cm. above the inferior border, 200 cc of reddish lumpy, thick, purulent material was evacuated.

Previous examination of the colon revealed no thickening, redness or edema. Drainage of the abscess was all that was attempted, because of the patient's condition. No amebas were found in the pus. Culture was negative. The patient convalesced rapidly. Following saline catharsis, March 14, motile amebas were found in the stool.

CASE 3—A. A., a white man, an accountant, admitted to Harper Hospital, Oct. 14, 1933, suffered a sense of dull pain and discomfort in the upper right part of the abdomen while playing golf, September 27. He had a slight chill while taking a shower but later ate his dinner and was up and about all the evening though he felt miserable. At 4 a.m. September 28, he was awakened with a sharp cramplike pain in the upper right quadrant which was relieved by an opiate. There was no nausea nor vomiting. There had been no increase of bowel movements or other abdominal distress. On that day his temperature reached 102. The pulse was 100. The pain continued off and on and was localized chiefly over the area of the lower ribs. Breathing aggravated the pain. Fixation of the right thorax with adhesive straps relieved the pain. The temperature slowly subsided and the soreness in the region gradually diminished. He was able to be about and finally on

the twelfth day his family physician, thinking that the condition might be due to a cholecystitis, sent him for a gallbladder dye roentgenogram. Following this exertion and the taking of the dye, his symptoms suddenly became aggravated and his temperature rose to 101. He had no colicky pain but the distress was more constant and prevented him from lying on either side. The pain shifted more to the axillary line and was higher than it had previously been. At this time he entered Harper Hospital. On examination there was evidence of a slight bulging in the liver region and marked tenderness over the costal margin. Through a rather thick abdomen could be felt an indefinable mass suggesting either an enlarged liver or an empyema of the gallbladder. There were no jaundice and no clay colored stools. A flat plate of the abdomen revealed a uniformly enlarged liver. The hemoglobin was 84 per cent, red blood cells 4,100,000, white blood cells 17,800 and polymorphonuclears 88 per cent of which 32 per cent were non-segmented and 56 per cent segmented. The Wassermann reaction was negative. The stools were negative for amebas and cysts. The urine was normal.

Operation was performed by Dr. Ballin, who made a median laparotomy incision from the xiphoid process down. The gallbladder was thin walled, grayish blue and without stones. The appendix was edematous, it was not removed. The colon was thickened and edematous, such as is seen in mild colitis. There was no abscess formation and the colon did not resemble a dysenteric colon. Adhesions covered the surface of the liver, which, when separated, showed a thin wall covering a large abscess in the convexity of the liver. Reddish pus without odor was drained from a cavity about 5 cm. deep and admitting three fingers. A portion of the necrotic wall was removed. The pus did not show any amebas. A portion of the necrotic wall of the abscess was removed for pathologic examination, which revealed necrotic liver tissue, containing occasional amebas.

The patient made an uneventful convalescence.

COMMENT

The symptoms of liver abscess as exemplified in these three cases consist chiefly of sudden pain in the upper part of the abdomen and over the costal area adjacent to the liver. It may radiate upward and to the shoulder or along the costal margin. It is aggravated by body movement, especially when the patient attempts to turn from side to side. Breathing increases the pain. Nausea and vomiting are characteristically absent. Chills may occur, though they are not uniformly complained of or regular in their occurrence. A moderate degree of fever is present usually of the continuous type. The pulse is rapid and soft. The leukocyte count is uniformly high. Schlaver⁶ and Fletcher⁷ have pointed out that hyperleukocytosis is usually present. (The former considers it a valuable diagnostic sign. In eleven cases he reported an average of 25,000 before operation was performed.) Jaundice may or may not be present, if so, it is slight. Sharp percussion over the ribs may elicit acute pain. Bulging of the upper right side or a tumor mass may be visible and palpable. An x-ray film may reveal an enlarged liver and suggest the abscess.

These three patients give a definite history of having eaten in an infected area in September and October of 1933. In the first two cases the day of infection must have occurred in the first week of October. It is especially noteworthy that they suffered no intestinal symptoms whatever and manifested no signs or symptoms of liver abscess until February, an interval of at least four months following the date of exposure to the contagion.

6 Schlaver, G. Hyperleukocytosis in Amebic Liver Abscess. *Minnesota Med. Wechschr.* 1903.
7 Fletcher, T. B. Study of Cases of Amebic Dysentery Occurring in Johns Hopkins Hospital. *J. A. M. A.* 11: 480-489 (Aug. 22) 1903.

The third patient might have become infected in July, August or September. As the date of onset was in September, the interval between the invasion and the beginning of his symptoms was of shorter duration. In each case the organism lay dormant in the intestine, exciting nothing more than a mild inflammatory reaction insufficient to produce symptoms. The invasion of the liver, as MacCallum⁸ has pointed out, probably took place through the portal vein. The abscesses were thin walled in each instance. No multiple abscesses were found.

SUMMARY

Attention is directed to the recent increased incidence of liver abscess. It is especially noteworthy that amebic abscesses may occur in individuals who have manifested no previous signs or symptoms of intestinal disturbances. It is deserving of emphasis at this time that this important sequel of amebic dysentery may appear months and even years after the original contact with the source of the infection, that immediate operation is important, and that preventive treatment should be rigidly carried out in cases of latent amebiasis.

TEMPORARY PHRENIC NERVE PARALYSIS

ITS ADVANTAGES OVER PERMANENT PARALYSIS IN THE TREATMENT OF PHTHISIS

JOHN ALEXANDER, M.D.
ANN ARBOR, MICH.

Surgical paralysis of the phrenic nerve has become so deservedly popular in the treatment of pulmonary tuberculosis that several thousands of such operations are now being performed in this country each year. Few physicians are aware that the function of the phrenic nerve may be stopped temporarily, for approximately six months, instead of permanently. During this time the clinical effect of the diaphragmatic paralysis may be tested and, if it is found to be unsatisfactory, the patient will again have the use of his diaphragm. If satisfactory, the paralysis may if necessary be made permanent or again be made temporary. Lack of this knowledge has caused widespread use of evulsion of the phrenic nerve or so-called phrenic exeresis or phrenicectomy, which produces an irrevocable paralysis of the diaphragm that has been shown by experience to be decidedly harmful to many patients.

The clinical results from phrenic paralysis are notoriously unpredictable. In some cases expected success is not realized, while in others healing of the lesions occurs when only improvement had been anticipated. Even when the disease is strictly confined to one lung, it is obviously undesirable that the patient should have a permanent paralysis of the diaphragm if this does not bring about the desired clinical effect. The importance of this is particularly evident in those many patients for whom a localized thoracoplasty of the upper ribs or an extrapleural pneumonolysis operation should later be used for cavernous lesions that the phrenic operation has failed to control.

When active tuberculous lesions are present in both lungs, the disadvantages of causing a permanent phrenic

paralysis are still more apparent. If this operation brings about healing in one lung and if the disease in the opposite lung progresses and later requires a phrenic paralysis, pneumothorax, extrapleural pneumonolysis or thoracoplasty, the expected reduction in vital capacity from the combination of the bilateral operations and bilateral pulmonary infiltration and fibrosis may be so great that the indicated operation for the opposite lung cannot be performed. I have seen many tragic instances in which a permanent phrenic paralysis has prevented the performance of a life-saving operation for lesions in the opposite lung which, at the time that the phrenic operation had been performed months or years before, had a relatively innocent appearance. This is especially true of young persons.

In bilateral lesions, a unilateral temporary rather than a permanent paralysis safeguards the patient's future and affords the physician wide latitude in the choice of future treatment. Bilateral apical thoracoplasty or extrapleural pneumonolysis in the presence of a single permanent phrenic paralysis might not leave sufficient reserve respiratory function to be safe. If a staged bilateral phrenic paralysis should be indicated and if the patient's vital capacity after the first operation should permit the second, the paralysis should be a temporary one on both sides, when diaphragmatic motion returns, a permanent paralysis might be performed on the side of the more advanced lesions if they have been satisfactorily influenced. For patients who require a bilateral phrenic paralysis for intractable hiccup, the temporary effect is obviously desirable, a number of cases have been reported in which both halves of the diaphragm have been permanently paralyzed.

A complicated but not rare condition, involving the use of phrenic paralysis and pneumothorax in bilateral tuberculosis, is importantly affected by the type of phrenic paralysis used. When bilateral lesions are sufficiently severe to require the use of bilateral collapse therapy measures, a permanent phrenic paralysis is sometimes wrongly first used on one side (e. g., the right) and a pneumothorax planned for the left side. If pleural adhesions should prevent the induction of the pneumothorax on the left and if the phrenic paralysis fails to control the lesions on the right, a left phrenic paralysis and a right pneumothorax would be indicated. If the right pneumothorax should need to be a large one, it might happen that this, together with extensive bilateral pulmonary infiltration and fibrosis and a coincident bilateral phrenic paralysis, would too greatly reduce the patient's vital capacity to be practicable. Had the right phrenic paralysis been a temporary one the desired plan of treatment could have been followed with relative safety after diaphragmatic movement had returned. The procedure that has just been outlined needs to be followed only if the patient should, mistakenly, have had a phrenic paralysis as the first collapse therapy measure. A far preferable plan in cases of bilateral severe lesions is first to attempt to produce a pneumothorax on the side of the more extensive lesions or the larger cavity and, if successful, use a temporary phrenic paralysis on the opposite side. If a pneumothorax cannot be induced, the phrenic paralysis should be used on this side and a pneumothorax attempted on the opposite side.

The examples that have been cited to illustrate the potential disadvantages of permanent phrenic paralysis are given with full realization of the fact that there are many patients with abundant respiratory reserve

From the Department of Surgery, University of Michigan Hospital.

who do well under the various conditions that have been cited, in spite of a permanent phrenic paralysis. Not every primary phrenic operation should be a temporary one. If there are many lesions throughout only one lung and an attempted pneumothorax has failed, a permanent phrenic interruption is indicated, perhaps preliminary to a thoracoplasty. Another important indication for permanent phrenic paralysis is when a pneumothorax is being abandoned over a lung whose function has been largely destroyed by tuberculosis and fibrosis.

The availability of temporary phrenic nerve interruption has greatly extended the usefulness of diaphragmatic paralysis. Both patients and physicians are willing to undertake this revocable operation as a test of its effectiveness for lesions in which the chance of arrest is only reasonably good and in which they would hesitate to accept a permanent paralysis. Furthermore, it greatly extends the range of bilateral collapse therapy. Although 20 per cent or more of patients having had the temporary operation need to have a second operation to make the paralysis permanent or perhaps to repeat the temporary paralysis, this is a small inconvenience when compared with the disadvantages and dangers of a primary permanent paralysis, whose effect has not been tested for the particular patient. The percentage of primary temporary phrenic nerve operations has steadily increased in my clinic during the past five years and at present approximately 90 per cent of the initial operations are temporary.

In brief, the temporary operation should be used whenever there is reasonable doubt as to the result and especially when further unilateral or bilateral collapse therapy measures may be needed that might unduly reduce the vital capacity if the diaphragmatic paralysis remained permanent.

The chief objection that has been offered against the temporary operation is that the period of paralysis is highly variable and that usually it is too short to have the desired effect on the lesions. It is true that the duration of paralysis is uncertain when only the main trunk is dealt with and the accessory phrenic roots are neglected. When the complete operation is done, a paralysis of approximately six months' duration results, in rare instances the paralysis is permanent. The objection that temporary paralysis is insufficient in duration to control the lesions is not sound in that a second operation may readily be used to paralyze the diaphragm permanently or temporarily, according to the effect of the initial operation.

The operation of temporary interruption of the phrenic nerve is but little more difficult than phrenic eversion. The main phrenic trunk (sometimes double or triple) is thoroughly crushed with a hemostat in only one place, if the length of crushed nerve should be the width of several hemostats, the phrenic nerve axons might be unable to penetrate so broad a defect in the nerve. In the great majority of patients one two or, rarely more small nerves will be found emerging from the anterior or mesial surface of the fifth cervical root of the brachial plexus at or above the level of the upper border of the clavicle and passing inferiorly and slightly mesially on the anterior surface of the scalenus anticus muscle. These nerves are accessory roots of the phrenic nerve although one may be the nerve to the subclavius muscle which often contains an accessory phrenic root. The accessory phrenic root or roots join the main phrenic stem in the superior mediastinum and if they are not crushed or resected they have a strong tendency

gradually to assume sufficient independent function to motivate the diaphragm, even though the function of the main phrenic stem has been completely blocked.

It is preferable to resect small accessory phrenic roots for a distance of approximately 2 cm rather than to crush them. They are too small to be needed for full resumption of diaphragmatic movement after the main phrenic nerve has regenerated. If they were merely crushed, it would be necessary to find them again if a second temporary operation were needed, and this would be difficult because of the presence of scar tissue that had formed in the field of the first operation (the large main phrenic trunk usually is not difficult to find).

If the second operation is performed to produce a permanent phrenic paralysis resection of 3 cm of the main phrenic trunk is all that is needed if the accessory roots were resected at the original operation. If the accessories had been crushed at the original operation their function would be destroyed if not less than 10 or 12 cm of the main trunk was evulsed, but evulsion or phrenic eversion is a painful operation and reported cases of fatal mediastinal hemorrhage, mediastinal emphysema and torn pleura should serve as a warning against it.

Dr John B. Barnwell of the Department of Medicine of the University of Michigan Hospital presented before the 1932 annual meeting of the American Association for Thoracic Surgery a number of the objections to permanent phrenic paralysis that have been considered in this article. He will later publish a detailed study of the subject. The present article is intended only as a preliminary presentation.

MALARIAL THERAPY IN SYPHILITIC INTERSTITIAL KERATITIS

J. V. AMBLER, M.D.

DENVER

AND

J. V. VAN CLEVE, M.D.

WICHITA, KAN.

Interstitial keratitis, which is a fairly common manifestation of hereditary syphilis, presents a major therapeutic problem to both the ophthalmologist and the syphilologist. That the usual antisypilitic treatment is inadequate is well known. Fisher,¹ in discussing the value of recent methods of treatment in the late stages of ocular syphilis, states that there is no evidence to show that treatment by either the older or the newer methods of antisypilitic therapy is capable of arresting or even of modifying the progress of the disorder. Others, including Stokes,² Carvill and Derby³ and Downing,⁴ maintain that arsphenamine reduces the time required for a cure and tends to prevent recurrences. More recently, bismuth preparations, particularly the soluble salts, have been shown to possess a distinct advantage over mercurial therapy. Wright and Perl-

man⁵ believe that the best treatment for interstitial keratitis consists in the conjoint use of neoarsphenamine and bismuth compounds. James⁶ recently reported six cases of interstitial keratitis successfully treated by a comparatively new preparation known as Stovarsol, (acetarsone N N R), but his results showed no great advantage over the better known methods.

From our own experience, it is believed that the therapeutic armamentarium against interstitial keratitis has been greatly increased by the aid of foreign protein therapy, especially intramuscular injections of milk or intravenous injections of typhoid vaccine. These observations concur with the opinions of Marchesani,⁷ Huber,⁸ Cowley⁹ and others.

Granting that the newer forms of antisyphilitic therapy possess an advantage over the older methods, especially if augmented by nonspecific protein therapy, there are still many cases of interstitial keratitis that respond very slowly.

During the last six years, seventeen patients with syphilitic interstitial keratitis have been treated by malarial inoculation at the Lakeside Hospital and the Cleveland City Hospitals. These have shown such uniformly excellent results that a report of the cases is considered justified.

The literature on the subject is meager. Although several foreign workers have reported excellent results by the method, there is apparently only one report relative to the subject appearing in the American literature. Dennie, Gilkey and Pakula¹⁰ in 1931 reported four cases of syphilitic interstitial keratitis treated by malaria, with rapid and excellent improvement in all four cases. They state that the improvement secured in from ten to twelve weeks was equal to the improvement secured in from six to nine months by other methods of treatment.

Schreiber,¹¹ one of the first to use malaria in the treatment of interstitial keratitis, in 1928 reported twenty-three cases treated by this method. He expressed the belief, after observing this series, that the course of the disease is greatly shortened and the iris more readily dilated but that the ground glass cornea is not changed. Marchesani⁷ successfully employed malaria in the treatment of interstitial keratitis. However, owing to the danger associated with the treatment, he later substituted typhoid vaccine. Other foreign authors who noted favorable experiences with the use of malaria in interstitial keratitis include Albrich,¹² Granstrom¹³ and Meller.¹⁴ All reports reviewed have been highly encouraging with the possible exception of one by Kufs,¹⁵ who saw a case of parenchymatous keratitis develop seven years after malaria therapy had been administered to a child with juvenile dementia paralytica.

TECHNIC EMPLOYED

Before malarial inoculation each patient is given a complete physical examination, and routine laboratory procedures are performed, namely, complete blood examination, blood Wassermann test, urinalysis and spinal fluid examination. As a rule, malarial therapy is not used in children under 11 years of age, because at this age the milder forms of fever therapy, such as typhoid vaccine, are usually quite successful. In our experience, young children tolerate malarial therapy poorly.

If no contraindication is found, from 5 to 10 cc of blood withdrawn from a patient undergoing malaria at the time is injected immediately into the vein of the recipient. With the onset of fever the blood pressure is taken twice daily, and blood counts are performed twice a week. Arbitrarily, the patient's condition is considered serious if the systolic pressure remains below 90 between the paroxysms or if the red blood count falls below 2,000,000, or a sudden marked increase in the number of malarial parasites is found in the blood smears. In uncomplicated cases from eight to ten chills are given. In patients showing a poor tolerance to malarial inoculation, due to daily paroxysms or other complications, a small dose of quinine sulphate (from 3 to 5 grains, or 0.2 to 0.3 Gm.) often will stop the chills temporarily, affording a rest of a few days, thus permitting the course to be completed. The malaria is terminated by administering quinine sulphate (10 grains, or 0.6 Gm., three times a day for from five to seven days).

All patients are given a high caloric diet, and fluids are forced. Local therapy, consisting of 1 per cent atropine, boric acid flushes and warm compresses to the eyes, is used throughout hospitalization.

REPORT OF CASES

CASE 1—J. D. L., a Negroess aged 11 years, admitted to the hospital May 28, 1926, complained of a severe bilateral interstitial keratitis of five weeks' duration. Both eyes showed a marked cloudiness of the cornea, circumcorneal injection, photophobia and lacrimation. Only light perception was present in the right eye. The blood Wassermann reaction was four plus. During the first three weeks of hospitalization, the patient received five intravenous injections, each of 0.1 Gm. of arsphenamine, eight mercury rubs and three injections of typhoid vaccine, without any apparent improvement. She was then inoculated with malaria and had fourteen chills. The acute symptoms rapidly subsided and when she was discharged from the hospital her eyes were remarkably improved. Follow up was unsuccessful and she was not seen again.

CASE 2—N. B. A., a white girl, aged 14 years, was admitted to the hospital July 28, 1926, with a diagnosis of congenital syphilis, juvenile dementia paralytica and interstitial keratitis. The eye trouble had begun one year before admission but had become much worse during the preceding two months. The child was poorly developed both physically and mentally. Both eyes showed marked photophobia. She had Hutchinson's teeth and rhagades about the mouth. The blood and spinal fluid Wassermann reactions were both four plus. The spinal fluid showed a trace of globulin and a cell count of thirteen. Inoculated with malaria on the day of admission, she was permitted to have eight chills. The eyes cleared remarkably after the fifth and sixth chills and continued to improve until they were apparently normal two months later. She was treated irregularly in the dispensary until Nov. 3, 1931, with no recurrences. The blood Wassermann reaction had become negative approximately two years after therapy was started. Permission for a repetition of the spinal fluid examination was refused.

CASE 3—L. H. A., a white woman aged 24, seen in the outpatient department in November 1923, had interstitial keratitis.

of the left eye. Arsphenamine and mercury were administered and she showed gradual improvement over a period of six months. In spite of continued antisyphilitic therapy the right eye became involved two years later. Treatment was continued without improvement for another year and on Nov. 26, 1926, three years after the onset of her illness, she entered the hospital for malarial therapy. There was extreme photophobia and lacrimation of the right eye. The left eye showed slight haziness of the cornea, otherwise it was normal. The teeth were Hutchinsonian in type. The blood Wassermann reaction was four plus. The spinal fluid was negative in all respects. The patient was inoculated with malaria and permitted to have nine paroxysms. Local therapy was not administered. After the fourth malarial chill there was a decided improvement in the appearance of the involved eye. Pain, photophobia and lacrimation completely disappeared. At the end of the malarial course the patient could distinguish objects with the affected eye, whereas before only light perception was present. The patient continued antisyphilitic therapy in the dispensary. Six weeks later, almost full vision had been restored. The blood Wassermann reaction became negative six months later. There had been no recurrence when last observed, May 26, 1932. Both corneas were perfectly clear and the Wassermann and Kline reactions on the blood were negative.

CASE 4—A S. A., a white girl, aged 7 years, entered the hospital, March 26, 1927, with interstitial keratitis of two months' duration. Examination showed diffuse cloudiness of both corneas and severe photophobia. No other clinical evidence of congenital syphilis was present. The blood Wassermann reaction was four plus. The spinal fluid was normal. The patient was inoculated with malaria and had three chills. During the third chill she became delirious and the temperature rose to 41.6 C (106.9 F). Because of her alarming condition, quinine and urea hydrochloride was given intramuscularly to terminate the malaria. In spite of her having had only three paroxysms, the eyes improved rapidly and she was discharged from the hospital two weeks later with both eyes apparently normal except for a slight haziness of the corneas. She was followed at regular intervals in the dispensary and received a total of fifty-one injections of arsphenamine, forty-two of a mercury compound and thirty-six of a bismuth compound, the last treatment being given Jan. 9, 1932. The Wassermann reaction became negative one year after the malarial therapy. When last seen July 12, there had been no recurrences, the vision was normal, and examination of the eyes showed no abnormality, except a small scar scarcely visible on the upper portion of the left cornea.

CASE 5—J. B. A., a white man, aged 20, was admitted to the hospital May 16, 1927. Three months prior to admission the left eye became red and painful. The pain had gradually become worse and was accompanied by loss of vision of the affected eye. Examination showed a fine cloudiness over the whole of the left cornea and a dense infiltration of the upper segment. The right eye was clear except for a mild conjunctivitis. The Wassermann reaction was four plus. He was inoculated with malaria and after the sixth chill it was terminated because of the extremely low blood pressure that developed. The eye improved rapidly and when the patient was discharged from the hospital, June 22, the photophobia and pain had disappeared and the vision was improved. The patient had never received any treatment previously nor has he received any treatment since the malarial inoculation. He was not seen again until almost five years afterward (Jan. 3, 1933), at which time no residue of keratitis could be seen and he stated that he had had no subsequent attacks in either eye.

CASE 6—E. P., a white man, aged 21, had been treated three months with arsphenamine and mercury for interstitial keratitis, during which time his symptoms had increased. His eye trouble had begun about one year before. Examination showed Hutchinsonian teeth and marked rhagades. The keratitis was so severe that he was able only to distinguish light from darkness. There were diffuse bilateral corneal opacities and ciliary injection. The blood Wassermann reaction was four plus. The spinal fluid was normal. Malarial therapy was instituted July 8, 1927, and a remarkable improvement was noted after the fourth chill. He was permitted to have four more chills after which he stated that he could see better than at any time

during the previous year. Two months after malarial therapy he had a mild flare up of interstitial keratitis, which subsided after two injections of sterile milk. He then received more or less regular antisyphilitic treatment until July 10, 1930, without further recurrences. When last seen, Jan. 3, 1933, the blood Wassermann reaction was negative and the eyes were normal.

CASE 7—F. S., a white girl, aged 14, admitted to the hospital, Oct. 3, 1927, complained of painful eyes and reduced vision. The right eye had become involved eight months before, the left eye became similarly involved only one month before. Examination showed right eye a nebulous opacity of the cornea, circumcorneal injection, marked conjunctivitis, and only light perception, left eye diffuse haziness over the cornea, moderate circumcorneal injection, and only light perception. She had Hutchinsonian teeth and a high (Gothic arch) palate. The blood Wassermann reaction was four plus. Without having any preliminary antisyphilitic therapy, she was inoculated with malaria and had seven severe paroxysms. The eyes made rapid improvement and she was discharged from the hospital, November 18, with but slight evidence of keratitis. Antisyphilitic therapy was then administered at weekly intervals for four years and the eyes have remained clear. She was last observed July 12, 1932.

CASE 8—A. B., a white man, aged 24, entered the hospital, June 1, 1928, complaining of sore eyes and loss of vision. He attributed his ailment to trauma of the left eye one week prior to admission. In the right eye there were numerous posterior synechiae and mild conjunctivitis. In the left eye there was a pteryctenule at the left side of the limbus, corneal vascularization, and only light perception. The blood Wassermann reaction was four plus. The spinal fluid examination was negative. The patient was inoculated with malaria and had fourteen chills. No improvement was noted until after the seventh chill. He then improved gradually until his discharge from the hospital July 20 when he was practically well. One month later the eye trouble returned, both eyes showing a typical interstitial keratitis. The patient was again hospitalized and showed gradual improvement with typhoid vaccine injections and arsphenamine therapy. He was discharged, October 10. November 12 there was another mild recurrence which again responded to typhoid vaccine. November 26, his eyes were clear and until last seen, Aug. 30, 1930, he remained well.

CASE 9—J. B., a white man, aged 22, entered the hospital, July 19, 1930, complaining of pain in the left eye and pain in the knees. Both symptoms had begun three weeks before. He had severe photophobia of the left eye with conjunctivitis and circumcorneal injection. The cornea was opaque. The right eye was normal. Both knees were swollen and tender, and the presence of fluid was demonstrated. The blood Wassermann reaction was four plus. A diagnosis of syphilitic hydrarthrosis of the knee joints (Clutton's joints) and syphilitic interstitial keratitis was made. Intensive antisyphilitic therapy, neoarsphenamine and bismuth compounds and shock therapy, typhoid vaccine, were administered. The knees rapidly improved but the keratitis gradually became worse and on October 10 the right eye also became involved. Neoarsphenamine, bismuth and mercury compounds, potassium iodide, typhoid vaccine and milk injections were continued until November 26, four months after admission to the hospital, at which time no improvement was noted in either eye. Visual acuity at that time was reported in the right eye as only light perception and in the left eye as 6/60. The patient was then inoculated with malaria, and after the fourth chill the improvement was so marked that the patient could see across the room with ease whereas before he had barely more than light perception. He was given ten malarial chills and was discharged from the hospital one week later. The patient returned regularly to the dispensary, where he received continuous antisyphilitic therapy, alternate courses of arsphenamine and bismuth preparations for eighteen months. Both eyes have remained clear and when last seen Nov. 8, 1932, only a few small corneal scars could be observed with an oblique light.

CASE 10—R. F., a Negress, aged 26, entered the hospital Dec. 12, 1930, with a bilateral interstitial keratitis and iritis of five months' duration. There was extreme photophobia and only light perception present in the left eye. With the right eye she could count fingers only within a distance of 4 inches.

Both eyes showed a marked conjunctivitis and a diffuse cloudiness of the cornea. The Wassermann and Kline tests of the blood were strongly positive. She had received no antisyphilitic treatment. The patient was inoculated with malaria but failed to have any elevation of temperature by the ninth day. However, malaria parasites were demonstrated in the blood smears. She was then given one injection of a sterile milk antigen, which activated the malaria, and there was a regular course of twelve chills. After the fourth chill there was a definite improvement, and by the sixth all subjective symptoms had subsided. When she was discharged from the hospital, Jan 11, 1931, both corneas were remarkably clear and she stated that her vision was as good as before the attack of interstitial keratitis. She was followed in the clinic at weekly intervals, where she received antisyphilitic therapy for twenty months. There was no recurrence and the vision has remained normal.

CASE 11—P B, a Negress, aged 35, was first seen at the Charity Hospital dispensary, Jan 14, 1931, with a marked interstitial keratitis of the left eye. There was no clinical evidence of congenital syphilis and no history of acquired syphilis. The blood Wassermann reaction was four plus. The spinal fluid was normal in all respects. She was given six injections of 0.4 Gm each of arsphenamine without improvement. She was then admitted to the Cleveland City Hospital, February 26, for more intensive therapy. The left cornea was of a steamy appearance, with sharply defined areas of exudate deep within the corneal substance. The right eye was normal, except for a mild conjunctivitis. She was treated with six 0.2 Gm doses of sodium bismuth thioglycollate and two typhoid vaccine chills, without improvement. She was then inoculated with malaria and allowed to have six paroxysms. There was an immediate response in the condition of the eye. She refused to take antisyphilitic treatment after her eye became well. When last seen Jan 3, 1933, she stated that she had had no further trouble with her eyes. There was a slight residual scarring of the upper and lower borders of the left cornea otherwise the eyes were normal.

CASE 12—J H, a white boy, aged 10 years, admitted to the hospital, April 23, 1931, complained of a bilateral interstitial keratitis of three weeks' duration. There was severe photophobia, both corneas were steamy to the point of opacity, with circumcorneal injection. The blood Wassermann reaction was four plus. No other clinical evidence of congenital syphilis was present. From April 23 to June 13 the patient received eleven injections of sodium bismuth thioglycollate, three injections of sterile milk and five intravenous injections of typhoid vaccine, without improvement. The patient was then inoculated with malaria and after six severe paroxysms he showed remarkable improvement. While the corneas were still cloudy all signs of acuteness had disappeared. He visited the clinic regularly until December 5, during which time the cloudiness of the corneas gradually improved.

CASE 13—E Z, a white woman, aged 21, entered the hospital, July 20, 1931, complaining that for one month the vision of the right eye had been blurred. There was a mild conjunctivitis of the right eye and a severe congestion of the blood vessels on the nasal side of the sclera. There was a dense opacity on the outer side of the cornea. The teeth were badly decayed and were suggestive of Hutchinson's type. There were rhagades about the mouth. The blood Wassermann and Kline reactions were four plus. An organic luetin test was strongly positive. The spinal fluid was normal. The patient was inoculated with malaria on the day of admission but remained afebrile for seven days. She was then given an intravenous injection of typhoid vaccine, which was followed by the beginning of the malarial chills. These continued regularly until quinine was administered, after the seventh chill. There was no change in the condition of the eye, until after the third chill, when a marked improvement was noted in the vision, and the subjective symptoms subsided. There had been no recurrence up to Nov 6 1932, fifteen months after malarial therapy. She received regular antisyphilitic treatment during this period of observation.

CASE 14—M M, a white girl, aged 17, had received more or less continuous antisyphilitic therapy for congenital syphilis from various physicians and clinics since the age of 1 year. The blood Wassermann reaction was said to have become nega-

tive at the age of 9, but because of frequent trouble with her eyes treatment was continued. The last attack of interstitial keratitis began one and one-half years previously, and in spite of continuous therapy her eyes had become progressively worse. Feb 18, 1932, she was referred to the Lakeside Hospital for malarial therapy. There was a marked blepharospasm, and both corneas presented the appearance of ground glass, with marked vascularization around the periphery. Only light perception was present in each eye. The blood Wassermann reaction was negative. The Kline test was three plus. The organic luetin test was strongly positive. No clinical evidence of congenital syphilis, other than the interstitial keratitis, could be demonstrated. Severe paroxysms started two days after malarial inoculation, and after the fifth chill the subjective symptoms abruptly ceased and the patient's vision had improved so greatly that she could recognize faces. The improvement continued steadily thereafter and after the eleventh chill, when the malaria was terminated, she could read coarse print. When last observed, seven months after the malarial therapy, there had been no recurrence and her vision was apparently normal. The haziness of both corneas was barely perceptible.

CASE 15—G H, a white woman, aged 21, entered the hospital May 29, 1932, because of a typical interstitial keratitis in the left eye of two months' duration. The left eye showed circumcorneal injection and complete opacity of the cornea. The right eye was apparently normal. She had Hutchinson's teeth. The eye became much less painful following the first malarial chill, and she was discharged, very much improved, after ten chills. No preliminary treatment was given, and only one injection of arsphenamine followed malarial therapy. In response to the follow up she was seen, Jan 3 1933, when the vision of the left eye was apparently normal and only a small corneal scar remained. The right eye had not become affected.

CASE 16—M W, a white girl, aged 19 entered the hospital January 15 1925, at which time a diagnosis of syphilitic periostitis of the tibia and of syphilitic interstitial keratitis was made. She was discharged without therapy, owing to lack of cooperation. Irregular treatment was administered which cured the periostitis but did not affect the eye condition. Nov 15 1931, she was readmitted because of the severity of the interstitial keratitis, which had become progressively worse during the six years. Again she was discharged without therapy. She then received antisyphilitic treatment from her physician until July 21, 1932, without benefiting the eye condition. She was readmitted, July 21, seven years after the onset of her illness. There was an intense photophobia and lacrimation of both eyes, and only light perception was present. Both corneas showed a dense cloudiness and vascularization. Malarial inoculation was performed and the patient was permitted to have eight chills. After the second chill the acute symptoms improved. When discharged she was much improved, although still unable to read large print. Both eyes continued to improve and when last seen, Jan 3 1933 she was able to read fine print without difficulty. No other treatment was administered after the malarial therapy.

CASE 17—T M, a white girl aged 15, entering the hospital, Oct 13 1932, complained that for the previous month she had suffered from a burning sensation and loss of vision in the left eye. She had received no antisyphilitic treatment. Examination showed the surface of the left cornea roughened. There were numerous irregular spots of infiltration over the central area in the deeper layers and a fine interstitial infiltration throughout the cornea. Only light perception was present. The right eye was normal. The blood Wassermann and Kline reactions were four plus. Other evidences of congenital syphilis were Hutchinson's teeth and a high arched palate. Following the fourth malarial chill the ocular condition began to improve. Eight chills were permitted and there was a gradual improvement noted each day. After her discharge from the hospital she visited the clinic for treatment and when last seen, Jan 3, 1933, she could read newspaper print with the affected eye. Only a small corneal scar could be seen. The right eye has remained uninvolved.

SUMMARY AND COMMENT

Seventeen patients with syphilitic interstitial keratitis, whose ages varied from 7 to 35 years, were treated by

means of malarial therapy, with uniformly good results. In every case the acute symptoms were relieved, usually early in the course of treatment. This rapid and complete cessation of pain, photophobia and lacrimation is emphasized as the most important finding of this study.

The final result in all cases was very good. Dennie and his co-workers,¹⁰ in their article on the antisyphilitic action of the malarial parasite in other than syphilis of the central nervous system, state that in old cases of chronic interstitial keratitis in which connective tissue is present in the cornea, no benefit could be expected from the use of malaria. All their cases were of comparatively recent origin when malaria was administered. From the results obtained in our series, it is found that malaria therapy is most gratifying when used in somewhat chronic cases. Four of the cases were of over one year's duration, case 16 having presented interstitial keratitis for seven years. In none of the cases was there a residual impairment of vision sufficient to cause an industrial handicap. Malaria is not advocated in cases showing only residual scarring of the cornea, but in chronic cases that still present pain and photophobia it invariably causes these symptoms to cease. It is believed that the corneal opacities are more rapidly and completely absorbed than with any other type of therapy.

Recurrences were noted in only two cases, in each instance they occurred a few weeks after the malarial therapy and responded well to the usual antisyphilitic treatment.

Five patients each had only one eye involved when malarial therapy was administered, in none did the second eye become involved.

Ten patients received varying amounts of antisyphilitic treatment prior to the malaria and seven had received no treatment of any kind. There was apparently no difference in the response of the two groups.

There were no fatalities, and in only one case did alarming symptoms develop which necessitated the termination of the malaria early in the course. This occurred in a child aged 7 years (patient 4), in whom the malaria was stopped after the third paroxysm.

CONCLUSIONS

Malarial therapy is considered to possess a distinct advantage over any other known treatment for syphilitic interstitial keratitis, and if proper safeguards are observed the associated danger is reduced to a minimum.

Whenever possible the patient with a resistant syphilitic interstitial keratitis should be given the benefit of malarial therapy in addition to the other usual forms of antisyphilitic treatment.

Beriberi—Vitamin B₁ is the factor which is lacking in diets capable of causing the disease beriberi. Its richest sources are the germ of cereals and yeast, but it is widely distributed in a number of common foods so that symptoms of frank deficiency are not found in those who partake of a mixed diet including such items as eggs, fresh meat, pulses and fresh vegetables and fruit. One of the earliest and most characteristic symptoms of deficiency of this vitamin is loss of appetite and in experimental animals this is followed by disturbances in the functioning of the alimentary tract generally. This observation has led to the suggestion that partial deficiency of vitamin B is a common cause of constipation and other irregularities of intestinal function. The evidence for this view is conflicting.—Colwell S. I. *Vitamins in Clinical Medicine, Practitioner* 132: 15 (Jan.) 1934.

PYRETHRUM SENSITIZATION

ITS IMPORTANCE AND RELATION TO POLLEN ALLERGY

SAMUEL M. FEINBERG, M.D.

CHICAGO

It is quite generally accepted now that the wind-borne pollens are responsible for the seasonal symptoms of hay fever and asthma. Insect-pollinated plants cannot be blamed for the causation of allergic manifestation by ordinary exposure. For these reasons the numerous insect-pollinated plants and flowers, among which are the roses, chrysanthemums, goldenrod and fruit trees, have been absolved from blame. However, some of these insect-borne pollens are toxic and are capable of producing allergic symptoms if contact with the mucous membranes is assured. In this group may be mentioned particularly the goldenrod and pyrethrum families.

The pyrethrum flower is a member of the large order of Carduales, to which the ragweeds also belong. Very close contact with the ordinary garden species of pyrethrum has been known to cause allergic reactions among gardeners. However, the most important source of allergy to pyrethrum is exposure to insecticides made from the latter. For this purpose commercial "Pyrethrum" is made by drying the flowers of *Chrysanthemum cinerariaefolium* and *Chrysanthemum coccineum*. In this material is to be found, of course, the pyrethrum pollen. Many of the common household insecticides, such as Black Flag and Flit, contain pyrethrum.

Apparently commercial pyrethrum contains three toxic principles. One is the pyrethrum ester, which gives this material its insecticidal properties and may result in symptoms of poisoning if ingested. This substance is peculiar to some of the species of pyrethrum flowers. A second toxic fraction is that responsible for dermatitis,¹ which may occur in the pyrethrum industries or among those handling insecticides or the pyrethrum flowers. This irritant is probably an oleoresin and is found in many of the members of the Carduales. The third toxic fraction is the specific allergen, which may give rise to symptoms of allergy, particularly in the respiratory tract.

It is curious that the importance and significance of allergy to pyrethrum has not been clearly emphasized in the literature. There are isolated reports of pyrethrum sensitization. Garratt and Bigger² in 1923 reported the occurrence of asthma attacks in a young woman following the use of insect powder on her bed. She gave a marked positive cutaneous reaction to the insecticide. They think that the powder contained pyrethrum. Ramirez³ in 1930 reported four instances of pyrethrum allergy. Although the protocols of his cases show definitely that in at least three there was clinical ragweed sensitization, he makes no reference to the possible significance of its relationship to pyrethrum sensitivity.

I have been impressed for a long time with the frequency of positive reactions to pyrethrum in ragweed sensitive patients. Possibly this has been evident because of the almost routine procedure I have practiced in performing complete skin tests with allergens.

other than pollen in hay fever cases in the last few years. The advisability of the latter procedure is evident when statistics show that in 79 per cent of the hay fever cases additional reactions were obtained to other nonpollen materials (including pyrethrum).⁴

In a series of 225 patients sensitive to ragweed pollen, 104, or 46.2 per cent, gave cutaneous reactions with extracts of the commercial pyrethrum. In another series of 114 allergic cases, chiefly of asthma and hyperesthetic rhinitis, which were not sensitive to ragweed, a two plus reaction to pyrethrum was obtained in only one instance. In view of the fact that the pollen in commercial pyrethrum is diluted considerably with other portions of the flower, it might be expected that the pure pyrethrum pollen would give an even higher incidence of positive reactions in ragweed sensitive individuals. In a few of the ragweed sensitive patients who gave negative cutaneous tests with pyrethrum, intracutaneous tests gave positive reactions. This appears to indicate that the 46.2 per cent incidence of reactions could be enhanced if a more potent extract were used. Gelfand,⁵ in tabulating the incidence of nonpollen tests in forty cases of hay fever, includes fourteen positive reactions to "insecticides" but does not discuss the nature of the insecticide, the method of testing or the significance of the reactions.

The foregoing considerations would make it appear that sensitiveness to pyrethrum is a group sensitiveness, occurs only in ragweed sensitive individuals, and is probably present in the majority of the latter. The following experiments substantiate further the fact that it is a group allergen or one closely related that is involved.

The serums of patients who gave good reactions to both ragweed pollen and pyrethrum extract were used to sensitize the skin locally in several nonallergic individuals. Subsequent testing of the sensitized sites with both ragweed pollen and pyrethrum gave positive reactions. This was, of course, controlled by obtaining negative tests on nonsensitized areas of the same individuals. The reactions to the ragweed pollen was obtainable with higher dilutions than those with pyrethrum, as may be expected by the source of extracts of the latter. Several of the sensitized sites were desensitized to pyrethrum by from one to three injections of the latter. These areas, when subsequently tested with ragweed concentrations that had given good reactions on nondesensitized sites, failed to show positive reactions. This indicates that desensitization to pyrethrum resulted in desensitization to ragweed pollen. In similar trials, sites desensitized to ragweed failed to react to pyrethrum. These experiments furnish additional evidence suggestive of a common or related allergen in ragweed pollen and pyrethrum.

Instances of allergic attacks from exposure to pyrethrum are too numerous to cite individually. I have observed attacks in many ragweed sensitive persons outside of the ragweed season. They have been due to bedbug powders, roach powders, fly sprays and even sprays used in keeping fleas from canaries. The point to be emphasized is that these are not unusual, rare or individual occurrences. The ragweed sensitive individual must be warned about these insecticides. It is possible that many of the unexplained attacks of hay fever or asthma occurring in winter in cases in which most of the symptoms are seasonal may be due to the

common and general use of pyrethrum in the form of insecticides.

SUMMARY

From the evidence of completely tested patients and experiments in passive transfer of reagins it is evident that at least one half of ragweed sensitive individuals are sensitive to pyrethrum, which in varying forms has a tremendous consumption and widespread use in the preparation of insecticides. The allergenic substances of ragweed pollen and pyrethrum are closely related. The important, significant and practical fact to bear in mind is that a potential one or two million of ragweed sensitive people in this country are susceptible to allergic attacks at any time of the year, as the result of exposure to pyrethrum products. This source of allergy is deserving of special emphasis and consideration.

THE LEUKOCYTE CONTENT OF THE BLOOD

FOLLOWING OBSTETRIC ANALGESIA PRODUCED BY PENTOBARBITAL SODIUM

ROBERT S. HARDWICK, M.D.

Fellow in Obstetrics and Gynecology, the Mayo Foundation
AND

LAWRENCE M. RANDALL, M.D.

ROCHESTER, MINN.

Pentobarbital sodium given orally has been proved an effective drug for producing analgesia during labor. It is generally considered that this drug has no observably deleterious effect on the infant and that the margin of safety for the mother with its use is great. It is possible to produce complete amnesia with massive doses of pentobarbital sodium, but satisfactory analgesia can be obtained among the great majority of patients by no more than 10 grains (0.65 Gm.) given during the course of the first stage of labor. As with any drug, the patient should be kept under close observation and the dose should be individualized to her needs.

There has been some discussion in the literature recently concerning the possible relation between the administration of barbiturates and the production of granulocytopenia. Madison and Squire¹ reported thirteen cases in which they thought granulocytopenia was probably due to the use of benzene chain derivatives. Watkins² recently discussed the possible part played by the barbiturates and amidopyrine in the causation of leukopenic states. As we have employed pentobarbital sodium in our obstetric practice among the majority of patients who were given analgesic agents other than a mixture of oxygen and nitrous oxide with the occasional addition of ethylene, we were naturally interested in the possibility that some deleterious effect on the leukocytes might be produced.

There are many reports in the literature based on studies of leukocytes during pregnancy, parturition and the puerperium. Moleschott³ and Nasse in 1854 seem

to have been the first to determine that there is leukocytosis during pregnancy. This has been confirmed by many investigators since, and there are numerous explanations for the condition. Virchow⁴ considered leukocytosis during pregnancy to be physiologic, and he believed that it might be the result of an increase in the size of lymph nodes and lymph vessels about the uterus. Dietrich⁵ has suggested that it is a reaction to the toxins of pregnancy.

It has been demonstrated that there is a definite increase in the number of leukocytes during labor. There is a shift to the left with a diminution in the number of lymphocytes, monocytes and eosinophils. There is also a considerable increase in leukocytes immediately after delivery, which reaches a peak according to most observers, at the end of the first twenty-four hours. At this time there is a marked shift of the neutrophils to the left, by the Arneth count, and also in Schilling's hemogram. Fauvet⁶ expressed the belief that leukocytosis in parturition is a "work leukocytosis." It is probable that a compensated acidosis exists during pregnancy and an uncompensated acidosis during parturition, and it has been shown that neutrophilic leukocytosis can be caused by acidosis. Experimentally, leukocytosis with a shift to the left can be demonstrated in acidosis caused by

administration of ammonium nitrate. Other drugs are known to affect the Arneth count. Ponder and Flint⁷ have demonstrated that administration to rabbits of thyroid extract, thyroxine and other substances produces leukocytosis, with a shift of the Arneth count. Nye and Barrs⁸ were unable to find any variation in the percentage of granular leukocytes after rabbits were strapped down for prolonged periods or after the use of amytal as an anesthetic agent. Given⁹ was unable to detect any change in the number of leukocytes following administration of chloroform during labor.

In an attempt to determine whether there was a deleterious effect on leukocytes after the doses of pentobarbital sodium which we commonly employ for obstetric analgesia, studies were carried out on a group of fifty-nine parturient women. Twenty-eight of these were primigravidas and thirty-one were multigravidas. An additional ten patients who were given no analgesic

agent other than mixtures of nitrous oxide and oxygen with occasional addition of ethylene were studied as a control group. The counts in the control group were all within limits that are accepted as normal for uncomplicated labor and puerperium and will not be referred to again. The number of leukocytes was counted, and

TABLE 2—Average Number of Leukocytes per Cubic Millimeter of Blood of the Fifty-Nine Parturient Women Concerned in Table 1

During Labor		Post Partum

10,366	9,182		9

a differential count performed during labor, before administration of pentobarbital sodium. These counts were repeated five hours post partum, ten hours post partum, and daily thereafter between 9:30 and 11 a.m. for ten days. In addition to pentobarbital sodium, which was given in doses (table 1) of from 1½ to 15 grains (0.1 to 1.0 Gm.), a mixture of nitrous oxide, oxygen and ethylene was administered during the last part of the second stage, colonic oil-ether was administered to four primigravidas and one multigravida during the first stage of labor.

As other observers have found there is a difference in the number of leukocytes of primiparas and of multiparas. The average number of leukocytes per cubic millimeter of blood for primiparas during labor was 12,550 and for multiparas (women in the second to the tenth pregnancy) 11,365 (table 2). The greatest leukocytosis was found five hours post partum, the

* Lymphocytes in thousands

† Neutrophils in percentages

average number of leukocytes per cubic millimeter of blood reached 20,342 for primiparas and 15,793 for multiparas. The averages ten hours after labor were 17,584 and 13,592, respectively. The average for each group gradually diminished until the fourth day post partum and was 10,733 and 9,319 respectively. From then until the ninth day the average remained constant, averages on the ninth day were 10,366 for primiparas and 9,182 for multiparas. The majority of observers have reported a more gradual tapering of the averages

⁶ Fauvet E. Beitrag zur Kenntnis der Schwangerschafts- und Geburtsleukozytose. Monatsschr. f. Geburtsh. u. Gynäk. 90: 220-228 (Jan.) 1932.

⁷ Ponder Eric and Flint K. N. Studies on the Arneth Count. Physiol. 16: 393-398, 1927.

⁸ Nye R. A. and Barrs V. A. R. Effect of Prolonged Strapping Down and of Amytal on the Distribution of Granular Leukocytes in Rabbits. Folia haematol. 47: 410-415 (July) 1932.

⁹ Given J. C. M. Hematology of Pregnancy and the Puerperium. J. Obst. & Gynec. Brit. Emp. 9: 261-267 (April) 1906.

Studies of differential counts corroborate the numbers reported in the literature. The neutrophils reach their peak five hours post partum among both primiparas and multiparas and gradually diminish to normal proportions after five days among primiparas and four days among multiparas (table 3). As the percentage of neutrophils increased, the percentage of lymphocytes decreased. The percentage of monocytes varied little. The percentage of eosinophils and basophils was not noticeably altered. According to the Arneth count and the Schilling hemogram, the neutrophils shifted to the left.

The temperature of two patients was elevated during the postpartum period. One of these patients had a temperature of 101 F. on the seventh day and the other a temperature of 100.6 F. on the third day. In neither case was the leukocyte count above the average for the rest of the group of fifty-nine patients.

SUMMARY AND CONCLUSIONS

There has been nothing in the behavior of the mother or infant in any case in which pentobarbital sodium was administered to indicate any deleterious effect. Studies of the blood from this group of patients give no evidence of the production of a leukopenic condition with the amounts of pentobarbital sodium administered. This series of studies of leukocyte and differential counts indicates that the greatest leukocytosis occurs at the fifth hour post partum. The level of leukocytes falls steadily to the fourth day, when the number of leukocytes per cubic millimeter of blood remains constant until the last examination on the tenth day.

THERAPEUTIC PNEUMOCOCCUS TYPE VIII (COOPER) SERUM

JESSE G. M. BULLOWA, M.D.
NEW YORK

Pneumococcus type VIII (Cooper) is identical with the Thomas strain (closely related immunologically to pneumococcus type III) described by Sugg, Gaspari, Fleming and Neill,¹ and the strain classified as pneumococcus IV A by Johnson of Pittsburgh, which was common in Pittsburgh in 1927. Georgia Cooper² published her description of pneumococcus type VIII in March 1929.

Pneumococcus type VIII is culturally distinct from pneumococcus type III, and the course of the pneumonia it causes is different from that induced by pneumococcus type III. Differentiation between type III and type VIII is readily made by the "swelling" reaction of Neufeld, specific rabbit serum being used for type III and type VIII, and by the colonies. The type III colonies are large and mucoid, the type VIII colonies are smaller, with more surrounding hemolysis.

Until July 1, 1933, my associates and I observed at Harlem Hospital 133 cases of pneumococcal pneu-

monia due to pneumococcus type VIII, in 122 adults and 11 children.³ Thirty-seven adult cases were treated with serum, twenty-seven were nonbacteremic and none of the patients died. Among eighty-five cases not treated with serum, seventy patients were nonbacteremic and nine died, a mortality of 12.8 per cent.

A factor determining the outcome in pneumococcus pneumonia is invasion of the blood stream. Apparently the amount of invasion is significant. Invasion with a few organisms, as revealed by growth in the broth with none or only a few organisms on the agar plates, is apparently of less significance. In several instances

† Two cases with colonies in postmortem blood excluded.

the organisms grew in chains. In one fatal nonserum case, chain formation present at first, was absent in later blood cultures.

Of the bacteremic cases, ten were treated with serum and two patients died, a mortality of 20 per cent, fifteen were treated without serum and five patients died, a mortality of 33 1/3 per cent.

In our nonserum cases, three patients died of the seven in whom a single colony occurred on agar or only the broth was positive. Two cases in which the organisms (in broth only) were recovered for the first time in postmortem blood from the heart were counted as nonbacteremic. In the serum series none of the five cases of slight invasion resulted fatally. Possibly the serum prevented severer invasion of the blood stream.

Among the more heavily invaded group that received no serum, there were eight cases and five deaths, in one of these cases, meningitis due to pneumococcus type VIII supervened three months after the pneumonia, which had been complicated with empyema.

In the serum group two of the four patients died. One had meningitis as well as pneumonia on admission, the other showed a marked reduction of the bacteremia after the serum but the treatment was discontinued because the stock of serum was exhausted.

The cases were accepted for treatment alternately in order of admission. There was no attempt to select early or favorable cases. Twenty-seven per cent of the serum cases were bacteremic, only twenty per cent of the nonserum cases were bacteremic.

The usual duration of the cases not treated with serum was from eight to nine days, most of the cases treated with serum terminated by the sixth day.

Twenty-nine cases treated with serum and thirty-six cases not treated with serum were studied for the presence of agglutination by the Sabin slide agglutination technic. The agglutinins were present much earlier in the serum cases than in the controls. The agglutinations were found as early as the third day in three cases treated with serum and on the fourth day in four cases not treated with serum. Agglutinins failed to develop in three cases not treated with serum. One of

From the Harlem Hospital Station of the Littauer Pneumonia Research Fund of New York University.

Our appreciation is expressed to loyal co-workers. Serum was produced through a grant from the Altman Foundation and the children were studied in part through financial assistance from the Commonwealth Fund. The Metropolitan Life Insurance Company assisted the study through its Influenza Commission.

1 Sugg, I. A., Gaspari, E. L., Fleming, W. J. and Neill, J. M. Studies on Immunological Relationships Among the Pneumococci. I. A Virulent Strain of Pneumococcus Which is Immunologically Related to but Not Identical with Typical Strains of Type III Pneumococci. J. Exper. Med. 47: 917 (June) 1928.

2 Cooper, Georgia. Edwards, Marguerite and Rosenstein, Carolyn. The Separation of Types Among the Pneumococci Hitherto Called Group IV and the Development of Therapeutic Antisera for These Types. J. Exper. Med. 19: 461 (March) 1929.

3 The increasing importance of pneumococcus type VIII is evidenced by the fact that during the current season in the nine months from July 1, 1933 until April 1, 1934 there have been in my service among the adults thirty-seven cases of pneumonia due to pneumococcus type VIII and one among the children in the pediatric service of Dr. Morris Gleich.

two fatal serum cases showed agglutinins on the third day, after this they were absent

The production of serum was commenced in 1928 in the laboratories of the New York City Department of Health. Seventeen horses have been under immunization, two have been immunized for more than two years. Four are being immunized at present. Miss Cooper reports that the mortality of the horses was unusually high, the titer of the antiserums comparatively low and the duration of immunization to obtain usable serum unusually long. The concentration procedure was the same as for type I serum.

At the Lederle Laboratories, Inc., five horses have been immunized. For from six to eight months they were immunized with pneumococcus types IV, V, VII and VIII, then types IV and V were discontinued. Three of the horses produced from 1,000 to 4,000 units against type VII, the same animals showed only from 100 to 200 units against type VIII. Two of these were carried from eighteen to forty-eight months.

Frequently we encountered thermal or anaphylactoid reactions with the first dose of serum in a patient though he did not react with a second and larger dose of the same serum given a few hours later. A patient receiving the same serum as previously may react to a subsequent dose of the same size with a chill.

CONCLUSIONS

The mortality was less in patients suffering from pneumococcal pneumonia type VIII treated with serum than in those treated without serum. The duration of the illness was shorter in the serum treated than in those who did not have serum.

Clinical Notes, Suggestions and New Instruments

BACILLUS WELCHII PANOPHTHALMITIS

SIDNEY WALKER, JR., M.D., CHICAGO

Infections from *Bacillus welchii* in different parts of the body are not uncommon, in fact, they are often encountered in industrial practice. The statistics give a high mortality rate. The previous war experience has done little to control this situation. Owing to the rapidity of the spread of the infection and the destruction of tissue thereby, it would naturally be assumed that such an infection in or about the eye would be fatal. Such apparently is not the case.

To date there have been ten cases reported in the literature: five in Great Britain, four in France and one in the United States. James¹ made the clinical diagnosis by gas bubbles in the anterior chamber and eviscerated the contents of the globe. Heath² had a case of panophthalmitis in which he eviscerated the contents. Cultures yielded positive results. Ridley³ had a case of gas gangrene and panophthalmitis twenty-four hours after a penetrating wound of the eye. He eviscerated the contents. Hamilton⁴ had two cases: the first on the third day after infection and the second on the fourth day. He eviscerated in both cases. Chailous⁵ had two cases and Darier⁶ also had two. All four eyes were enucleated.

Berry⁷ of Brooklyn had a patient who had been hit in the right eye by a chip from a nut and eighteen hours thereafter an active panophthalmitis developed. A roentgenogram showed

a foreign body 2 by 4 mm and 20 mm back. Gas bubbles filled the whole anterior chamber and he reports that a dark substance followed the knife out of the wound. Two days later the eye was enucleated and laboratory examination was positive for *B. welchii*.

REPORT OF CASE

T. V., a man, aged 35, an automobile mechanic, referred to my office, Nov. 1, 1933, by Dr. Carls, had hit his left eye with something while pounding on an axle shaft of an automobile. He did not seek treatment until the following morning and when I saw him that day he had an intensely inflamed left eye with a beginning hypopyon. There was a small corneal wound at 5 o'clock on the dial near the limbus. The lens showed beginning cataract and no view of the deeper structures was possible on account of the cloudy media and lens changes. What appeared to be a very small bubble was seen in the anterior chamber at this time. A roentgenogram showed a piece of steel 1 by 3 mm, 10 mm back. The patient was sent to the hospital and the corneal wound was slightly enlarged with a cataract knife, which, when it was withdrawn, was followed by a coffee ground-like discharge. The magnet point was introduced and the steel extracted. Foreign protein was given and the patient was put to bed. In twenty-four hours there was a very marked panophthalmitis with boardlike induration of the bulbar conjunctiva. Evisceration of the globe was done at once and a drain inserted. Massive doses of *B. tetani* and *B. welchii* serum were given. The drain was left in for four days and hot moist compresses were applied to the socket. The patient made an uneventful recovery and left the hospital on the twelfth day.

Pus was taken from the eye for culture November 6. A specimen of 1 cc of thick yellow pus was sent to the laboratory. Gram stain showed many leukocytes. Frequent gram-positive, blunt bacilli both large and small were seen. Amorphous material and erythrocytes were present. With the Ziehl-Neelsen method no acid-fast bacilli were seen.

The specimen was inoculated on aerobic blood agar plates, endo plates, semianerobic blood agar slants and anaerobic blood agar slants. There was no growth of organisms in seventy-two hours.

The specimen inoculated into litmus milk under anaerobic conditions produced rapid acidification and coagulation. The production of a large amount of gas and a characteristic stormy fermentation was noted in twelve hours, at a temperature of 37°C.

A small amount of the specimen was inoculated into anaerobic beef heart broth and again a considerable production of gas and turbidity of broth were noticed. Stained smears of the litmus milk and beef heart broth demonstrated the presence of very large, thick gram-positive bacilli.

Solid dextrose agar tubes showed further the violent production of gas and isolated colonies of the gram-positive bacilli obtained. The organism was identified culturally as being *B. welchii*.

COMMENT

Jordan's textbook on bacteriology states that gas gangrene nearly always consists of mixed aerobes and anaerobes of several species. Cultures of *B. welchii* do not blacken brain and meat cultures normally, but the presence of metallic iron produces discoloration. This fact may and probably does explain the coffee-like secretion that was noted by Dr. Berry in his case and also in mine.

The striking thing is the rarity of *B. welchii* in perforating and lacerated wounds of the eye. During the last thirteen years I have operated on more than 400 patients with intraocular steel and as many with penetrating and lacerated wounds of the eye but this is my first case of *B. welchii* panophthalmitis. Most of these patients are from industrial plants and are exposed to different types of infection. Physicians in general industrial practice not infrequently have cases of *B. welchii* infection yet this is only the second reported case of ocular infection in the United States. The further fact that the mortality in *B. welchii* infection in other parts of the body is so high and yet in ten known cases of *B. welchii* in eye injuries there have been uneventful recoveries in every case is worthy of note and may be explained by the absence of muscle tissue infection. With the venae vorticosae and the deep ciliary

vessels in close proximity, and possible exposure of the meninges through the optic nerve sheath, why there are no fatal cases is difficult to explain. Possibly earlier diagnosis and early removal of offending tissue may account for a portion, yet that in itself is not enough.

CONCLUSIONS

- 1 Intra-ocular steel is a potential carrier of *B. welchii*, even though rare.
- 2 Early diagnosis is apparently of prime importance.
- 3 *B. welchii* panophthalmitis apparently has not the grave prognosis that this infection has in other parts of the body.
- 4 The fact that the infection is limited to nonmuscular tissue may offer a better prognosis.

OTOMYCOSIS REPORT OF CASE

OMAR C. AMSTUTZ, M.D., BELLEFONTAINE, OHIO

Among patients presenting themselves for treatment in southern Florida, particularly during the six weeks following the hurricane of Sept. 17 and 18, 1926, it was reported as not unusual for three or four new cases of otomycosis to be seen every day. In this locality, however, otologists of wide experience covering a number of years were certain that they had never recognized a case.

REPORT OF CASE

A woman, aged 23, a schoolteacher, complained that her left ear hurt, felt full and was slightly deaf. A dirty whitish layer was observed covering the drum and part of the adjacent auditory canal. A few drops of 5 per cent phenol in glycerin were placed in the ear and the patient was ordered to return. When the ear was examined two days later a few small black dots were visible, one of which was removed on the point of a paracetic bistoury. Microscopic examination confirmed a suspicion that it was a mold sporangium with its unbranched hyphae.

The remaining matted feltlike, mycelial mass was easily removed by irrigation with weak sodium bicarbonate solution and 10 drops of 70 per cent alcohol was placed in the external auditory canal. With the idea that, if the systemic use of iodides in such cases or even in pulmonary aspergillosis is justifiable, their local use might also be effective I dropped a weak mixture of potassium iodide in water and tincture of iodine into the ear. Seven days later however there was additional mycelial growth to be removed by irrigation. At this time daily instillations of 2 per cent salicylic acid in 95 per cent alcohol were instituted for one week and then weekly for one month at which time only a hard dry scaly material remained in the ear. Instillations of 5 per cent phenol in glycerin were resumed for a short while to loosen the material. The condition has not recurred during a three year period.

Through the courtesy of Dr. W. J. Kostir of Ohio State University, a potato culture transplant of the mold was identified as a mixture of *Aspergillus niger* (sooty mold) and *Rhizopus nigricans* (bread mold), of which the latter may or may not have been a contaminant.

Cultures were made on various mediums all showing a fairly luxuriant growth. This was interpreted as indicating that the organism was not highly specialized for a life in contact with living tissues and was thus only secondarily pathogenic.

Potato cultures were arbitrarily selected and treated with such substances as sweet oil, castor oil, glycerin and water to determine any possible effect of materials that people commonly use in their ears. No effect was noted. Other such cultures were treated with 70 per cent alcohol, 2 per cent salicylic acid in 95 per cent alcohol and 5 per cent phenol in glycerin. The alcoholic solutions exhibited an inhibitory and even a fungicidal effect. Certain other such cultures were treated with weak iodine solutions, which may have had some minor effect in delaying the formation of sporangia. This would hardly invalidate the systemic use of iodides.

COMMENT

Molds are known to grow better in acid than in alkaline mediums. It would therefore seem more rational in such cases

as this to irrigate with warm dilute sodium bicarbonate solution rather than with the commonly used boric acid solution. Moisture being necessary for mold growth, such irrigation should be followed by a strong alcoholic solution. An alkaline alcoholic solution might well form the basis of a new form of treatment. One author with a commendable view toward the comfort of his patient follows irrigation by instillation of 10 per cent cocaine in 1,000 epinephrine solution.

If as is believed, spores will not germinate in a normally healthy meatus but require some form of exudate on which to grow, the nonmycotic condition producing such an exudate may remain to be treated even after each spore or hypha is definitely killed. If this is true, silver nitrate is said to be one of the best antiseptics and astringents. If the growth has penetrated deeply into the epithelium, however, no single treatment can be trusted to bring about a complete cure.

While in this case the prognosis was favorable, it is more grave if the drum is perforated, as the organism may enter and develop in the tympanic cavity and even in the mastoid cells. Although early diagnosis may make appropriate treatment more rapidly effective, many cases are delayed because even extensive invasions may take place without subjective symptoms.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

H. A. CARTER, Secretary

SUPER SELF-CONTAINED KROMAYER LAMP ACCEPTABLE

The Super Self-Contained Kromayer Lamp is manufactured by the Hanovia Chemical and Manufacturing Company, Newark, N. J. It is a water-cooled quartz mercury vapor arc lamp and is recommended for local application of ultraviolet radiation as a therapeutic measure.

Super Self-Contained Kromayer Lamp

The burner is a high pressure low voltage, mercury vapor arc enclosed in a transparent fused quartz envelope. This burner is surrounded by a double wall casing. Cooling water circulates between the walls, thus carrying away the excess heat generated by the burner. Two small circular quartz windows in the double wall casing (window in each wall) permit the passage of ultraviolet and visible radiation, but since the rays pass through the cooling water, the heat radiation is greatly inhibited. The unit is useful where close application to the skin is desirable. Suitably shaped quartz rods may be attached to the window, enabling the transmission of ultraviolet rays to inaccessible places.

The electrical characteristics are as follows:

Alternating Current

Line voltage 105 to 120 volts (60 to 25 cycles)
Starting amperage 10 amperes
Operating amperage (5 amperes 220 volt line)
(7 amperes 115 volt line)
Maximum burner voltage 120 volts
Minimum burner voltage 100 volts

Direct Current

Line voltage 220 volts
Operating amperage (120 volts 5.5 amperes)
(220 volts 4.5 amperes)
Starting amperage 10 amperes
Maximum burner voltage for 110 volt burner 70 volts
Minimum burner voltage for 220 volt burner 120 volts

One unit was investigated in a clinic acceptable to the Council. The claims for the product meet the requirements of the Council as stipulated in the Official Rules. The Super Self-Contained Kromayer Lamp, therefore, is included in the Council's list of acceptable devices.

LEPEL HIGH FREQUENCY COMBINATION MACHINES AND ULTRAVIOLET LIGHT ATTACHMENTS ACCEPTABLE

The Lepel High Frequency Laboratories Inc of 39 West Sixtieth Street, New York, manufactures the following equipment

Model 300 Lepel High Frequency Combination Machine designed for medical diathermy, surgical currents including underwater cutting, coagulation, desiccation, and for energizing ultraviolet generators for local or general irradiation (fig 1)

Model 310 this model being the same as 300 except that it is not equipped with cutting currents

Model 510, Electro Surgical Machine designed for surgery, cutting under water, cutting in air, coagulation, desiccation and also energizing Lepel Hand Lamps

Model 600 and Model 610 Lepel Coagulators for diathermy, coagulation, desiccation and autocondensation in combination with Lepel Cold Ultra Violet Light

Model 700 and Model 710 Short Wave Generator with Lepel Internal Ultra Violet Quartz Hand Lamps and Model 900 2 and Model 900 4 Multiple Diathermy Machines. The Multiple Diathermy Units are for hospital and physician's use

One complete unit was examined in a laboratory and in clinics acceptable to the Council on Physical Therapy. The laboratory report on the machine indicated that the mechanical make up and the electrical construction met the Council requirements for diathermy machines as published in THE JOURNAL Sept 2, 1933, page 776. The temperature rise in the transformer remained within the limits as specified by the American Institute of Electrical Engineers. The condensers, conductors, reactors, ammeter and wiring were reported satisfactory.

The firm claims that these machines will generate high frequency electrical currents in ample quantities for medical diathermy, autocondensation, coagulation and desiccation and that they will generate sufficient surgical cutting currents for use in both air and water. The Council's investigation substantiated these claims. The more powerful units are equipped with ultraviolet generators energized by high frequency currents produced by the diathermy machine. These ultraviolet lamps are designed

for both general and local irradiation. The ultraviolet equipment was investigated in a laboratory acceptable to the Council, and the report reads as follows:

The following data were obtained on the Lepel Ultraviolet Lamp

The device examined consists of a high frequency diathermy machine with attachments for operating an assortment of lamps

The lamp examined consists of a spherical quartz or Corex D bulb, about 3 inches (7.5 cm) diameter which is placed within a helical conductor that carries a high frequency current obtained from the transformer in a diathermy machine. The bulb is evacuated and contains a globule of mercury. There are no electrodes sealed into the bulb. The mercury vapor within the bulb is excited to luminescence by the high frequency electrodeless discharge from the 5000 volt secondary of the transformer, which discharges through the helix.

The emission spectrum is essentially that of the neutral mercury atom similar to that of the mercury arc (e.g. the Lyman) though close to the walls of the bulb there are some weak spectral lines, not present in the hot quartz mercury arc lamp. The spectral energy distribution and the erythemogenic efficiency of this lamp were found to be closely the same as that of the ordinary quartz mercury arc lamp. Practically the only difference is the energy flux density (intrinsic brightness) owing to the fact that in the quartz mercury arc lamp the luminous discharge is concentrated in a column that is less than 10 mm diameter, whereas in the electrodeless discharge the radiation fills the entire bulb 6 to 8 cm in diameter.

The primary of the transformer in the diathermy machine was operated on 115 volts 60 cycles under which conditions by a suitable regulating device the milliammeter in the secondary indicated the current in the secondary required to operate the lamp, the normal currents being 3000 milliamperes for the hand lamp and 4200 milliamperes for the body lamp.

Fig. 1—Lepel High Frequency Combination Machine

Two kinds of lamps, a "hand lamp" and a "body lamp" and two kinds of lamp bulbs (of quartz, and of Corex D glass) were tested.

The following is a summary of the radiometric measurements of the ultraviolet radiant flux ($U \cdot V \cdot Q$) in microwatts per square centimeter ($\mu W/cm^2$) of wavelengths shorter than and including 313 millimicrons, emitted by these lamps.

I Hand Lamp Quartz Bulb

On 3000 M A $U \cdot V \cdot Q = 161 \mu W/cm^2$ at 24 (61 cm)
 $= 403 \mu W/cm^2$ at 12 (30.5 cm)
 Erythemogenic efficiency = 0.351 I E U = 57 $\mu W/cm^2$ for a 15 min exposure
 $= 14 \mu W/cm^2$ for a 60 min exposure

II Body Lamp Corex Bulb

On 4200 M A $U \cdot V \cdot Q = 242 \mu W/cm^2$ at 24 (61 cm)
 Erythemogenic efficiency = 0.272 I E U = 73 $\mu W/cm^2$ for a 15 min exposure
 $= 18.5 \mu W/cm^2$ for a 60 min exposure

III Body Lamp Quartz Bulb

Distance 24 (61 cm)
 On 4200 M A $U \cdot V \cdot W = 543 \mu W/cm^2$
 4000 M A $U \cdot V \cdot W = 494 \mu W/cm^2$
 3800 M A $U \cdot V \cdot W = 450 \mu W/cm^2$
 3500 M A $U \cdot V \cdot W = 357 \mu W/cm^2$
 slightly luminous
 $= 25 \mu W/cm^2$
 Erythemogenic efficiency (normal operation 4200 M A)
 $= 0.313, I E U = 64 \mu W/cm^2$ for a 15 min exposure,
 $= 16 \mu W/cm^2$ for a 60 min exposure

From the foregoing data it follows that

the Hand Lamp emits $(161 + 57) = 218 E U$ (Quartz bulb)
 the Body Lamp emits $(242 + 73) = 315 E U$ (Corex bulb)
 the Body Lamp emits $(543 + 64) = 607 E U$ (Quartz bulb)

From this it appears that at a distance of 24 inches (61 cm) from the center of the bulb in its reflector, the time to produce a minimum perceptible erythema is as follows: the hand lamp with quartz bulb 53 minutes, the body lamp with Corex bulb 45 minutes, and the body lamp with a quartz bulb, 175 minutes.

This is in good agreement with the manufacturer's claims for effectiveness in producing an erythema. As already stated, the spectral energy distribution of these two lamps is practically the same as that of the hot quartz mercury arc lamp. These two lamps are eligible for acceptance on the same basis as other quartz mercury arc lamps already accepted by the Council.

Small generators of ultraviolet radiation have been designed by the firm which are said to be useful in irradiation of the nose, sinus, trachea, middle ear, larynx, bladder, kidney, urethra, colon and stomach. The small lights come in diameters of 3, 5, 7 and 9 mm. The high frequency electric current generated by the units energizes the miniature quartz lamp bulbs,

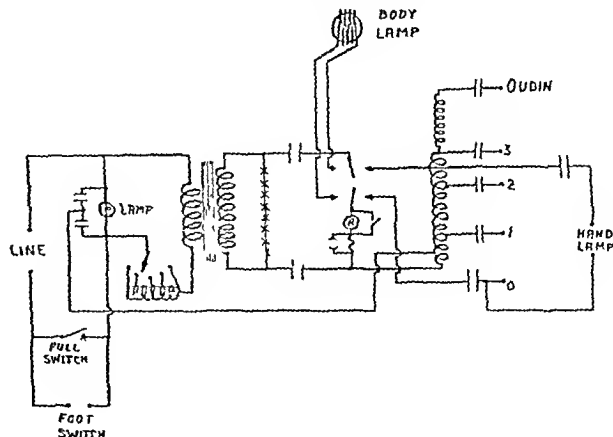

Fig. 2—Schematic diagram of circuit

which are mounted on the end of wired catheter tubes so that they can be inserted into small cavities. The firm claims. The Council has not received critical evidence substantiating the therapeutic value of these lamps and therefore does not recommend them for therapeutic purposes. However, the ultraviolet generators designed for general and official irradiation are acceptable. Figure 2 is a schematic diagram of the circuit.

As an adequate generator of high frequency current for medical and surgical diathermy, the unit appears satisfactory. The Council therefore includes the Lepel High Frequency Combination Machine and Ultraviolet Light Attachment in its list of accepted devices.

Council on Pharmacy and Chemistry**NEW AND NONOFFICIAL REMEDIES**

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

DI-HYDRANOL NOT ACCEPTABLE FOR N N R

Di-Hydranol was first presented for the Council's consideration by the manufacturer Sharp & Dohme, Inc, under its chemical name 2-4 dihydroxy phenyl n-heptane (June 25, 1930). At that time the firm stated that the substance was to be used as an "intestinal antiseptic" but gave no statement as to dosage or mode of administration. There was no mention of the name Di-Hydranol in that presentation. The product was again presented (Oct 7, 1930), this time under the name Di-Hydranol. The claims were as follows

- (1) Di Hydranol is more than 100 times as bactericidal as phenol
- (2) It is only absorbed to a small extent from the intestinal tract
- (3) It possesses a definite selective action against Gram positive organisms including the putrefactive flora of the intestine

The Council questioned whether the name Di-Hydranol is satisfactory and concluded (a) that the name Di-Hydranol be considered satisfactory for the product when and if it is accepted with the further approval of Leonard and Feirer¹ or others if necessary and the adoption of heptyl resorcinol as a synonym (b) that consideration of acceptance await evidence of its clinical effectiveness. The name was proposed by Leonard and Feirer¹ in 1931.

In a further report the Council raised the question of the clinical value of Di-Hydranol and pointed out that the paper of Leonard and Feirer¹ which was presented by Sharp & Dohme as evidence of the drug's usefulness as an intestinal antiseptic, was not sufficient to substantiate the claims made for the product. The Council voted that Di-Hydranol be held unacceptable because of lack of evidence of its clinical usefulness and adopted a statement setting forth the facts here summarized. However as a result of a letter (May 5, 1931) from Sharp & Dohme in which the firm acceded to this action of the Council, the Council voted to postpone publication of the statement of its consideration of Di-Hydranol and to postpone consideration of the product. The firm agreed to desist from active propaganda for Di-Hydranol to obtain further evidence of its usefulness from practicing physicians and to revise the labels and pamphlet in accordance with changes suggested by the Council.

Nov 23, 1933 the secretary of the Council wrote to Sharp & Dohme requesting clinical evidence current advertising and

labels. In reply to this letter Sharp & Dohme wrote (Dec 6, 1933)

"We have corrected our labels and booklet according to suggestions from the Council as you will note from the three copies of each we are enclosing with this letter."

We have supplied hundreds of clinical report blanks referred to in our letter of May 5 [1931], to physicians and have received dozens of favorable clinical reports from them on the use of Di-Hydranol but we now realize such reports would be looked upon by the Council as simply an expression of opinion from physicians and not acceptable clinical data. With this in mind we have since supplied an abundance of material to various investigators in most cases connected with medical schools but the gathering of properly controlled scientific clinical tests involves considerable expenditure of money which in many instances the institutions lacked during the past few years and which we were unable to supplement and keep within our budget requirements.

We have just been advised that an investigator located in Chicago has completed his preliminary survey with Di-Hydranol and that his results were so satisfactory he intends reading a paper on the subject in the spring in Cleveland and we understand this will be published at a later date. Obviously the results of this experimental work are not available for us to submit to the Council at the present time.

Inasmuch as we never have made any other claim than that Di-Hydranol destroys the putrefactive flora of the intestinal tract we suggest that the Council accept Di-Hydranol with the provision we make no claims other than that stated above and neither will we until we can submit acceptable clinical evidence to substantiate any further claims.

It will be noted that in the last paragraph the firm suggests acceptance of Di-Hydranol by the Council with the understanding that the only claim made for it be that it destroys the "putrefactive" flora of the intestinal tract.

Later, evidence became available that the firm is now circulating the profession on Di-Hydranol.

The labels and advertising booklet submitted by Sharp & Dohme, Inc, are in the same form as those revised according to their letter of May 5, 1931, and submitted to the Council on May 8 and May 14, 1931.

The labels indicate that the dosage forms are

- (a) 5 per cent solution of Di-Hydranol in olive oil
- (b) Soluble elastic capsules 0.15 Gm Di-Hydranol (a 25 per cent solution in olive oil)

The chief claim is stated on the label for the capsules as follows: "A powerfully germicidal substance possessing a selective bactericidal action against the putrefactive flora of the intestinal tract."

The first two sections of the booklet deal with the origin and chemical composition of Di-Hydranol. The third section, headed "Bactericidal Activity" makes the claims already considered by the Council. In addition, the last sentence of this section also mentions the possible use of Di-Hydranol as a protozoa acid drug.

The next section of the booklet deals with toxicity. The statement is made that in seventy-nine adults receiving repeated doses of Di-Hydranol in elastic gelatin capsules of olive oil solution no toxic result was observed except the occasional occurrence of slight diarrhea or constipation. In the next section, dealing with excretion the following statement is made:

When administered by mouth the bulk of each dose of Di-Hydranol passes through the alimentary canal unabsorbed and may be detected in the stools by Barbour's test (5). The drug appears in the urine in easily detectable concentration only after massive doses. The fact that Di-Hydranol remains largely unabsorbed first suggested its use as an intestinal antiseptic.

The remainder of the booklet summarizes the work of Leonard and Feirer¹ on the control of intestinal putrefaction in man by the oral administration of Di-Hydranol. This paper will be summarized and discussed later in this report. The last paragraph of the booklet states the indications for the drug as follows:

Di-Hydranol is indicated therefore in the treatment of cases in which benefit to the patient may be anticipated from the elimination of the putrefactive flora.

Hampil² has determined the phenol coefficient according to the U S Hygienic Laboratory method of the series of alkyl resorcinols to which heptyl resorcinol belongs. This author found that amyl hexyl, heptyl and octyl resorcinols have the greatest bactericidal activity and that the activity of hexyl heptyl and octyl resorcinols is greatly enhanced at 37 C. The decreased activity of compounds with longer carbon chains is

¹ Leonard V and Feirer W A Bull Johns Hopkins Hosp 48 25 (Jan) 1931

² Hampil B J Infect Dis 43 25 (Jul) 1928

presumably due to insolubility, for increase of temperature and alkaline reaction, both of which increase the solubility, also increase the bactericidal activity. The presence of gelatin as other protein material decreases the bactericidal activity of resorcinols considerably and with heptyl resorcinol this decrease is almost 90 per cent. In the light of the latter observation the statement in the advertising pamphlet that Di Hydranol has a bactericidal activity 100 times that of phenol at body temperature is rather misleading since the compound must act in the intestine in the presence of proteins and protein split products.

The alkyl resorcinols, especially hexyl, heptyl and octyl resorcinol, have a selective action on many bacteria belonging to the gram positive group as demonstrated in vitro by Hampil³ and in vivo by Ratchliffe⁴ and Leonard and Feirer.¹ Ratchliffe showed by means of bacterial plate counts on stools that the gram positive organisms of the acidophilus group are eliminated from the intestinal flora of rats under treatment with butyl, hexyl, heptyl and octyl resorcinols and that the gram-negative lactose fermenters of the coli-aerogenes group then become predominant. Leonard and Feirer appear to have shown the elimination of gram-positive spore forming anaerobes from the intestinal tract of human beings treated with heptyl resorcinol (Di-Hydranol). It is possible that these organisms were not always destroyed in the intestine but failed to grow in the stool cultures because of the bacteriostatic or bactericidal action of Di-Hydranol excreted in the feces. This point needs further investigation.

The toxic effects of Di Hydranol are those of alkyl resorcinols in general. Eustis⁴ reports colic and nausea with occasional vomiting in some of the cases treated with the drug in olive oil. Faust⁵ reports that the toxic effects in human beings are negligible. David and Johnstone⁶ report one case out of thirteen treated in which a number of watery stools followed the administration of Di Hydranol. All investigators seem to agree that the drug is too irritating to be given in the crystal line form but phenylsalicylate coated pills or olive oil solution may be administered in large amounts without serious toxic symptoms.

Robbins⁷ has made quantitative studies on the absorption and excretion of hexyl and heptyl resorcinol in dogs. This investigator found that after the administration of 1 Gm doses by mouth of crystalline hexyl resorcinol an average of 67 per cent was recovered from the feces and 29 per cent from the urine. Heptyl resorcinol was absorbed to a much smaller extent, 96 per cent being excreted in the feces and only 1 per cent recovered from the urine. When hexyl resorcinol is given in olive oil excretion in the urine is reduced from 29 per cent to 17 per cent. The drugs were recovered in the free state from the feces but the compounds excreted in the urine were in a nonbactericidal conjugated state. So far these observations coincide quite well with the claims made by the manufacturers of Di-Hydranol.

The claims of Sharp & Dohme Inc. for the use of Di Hydranol as an intestinal antiseptic are based largely on a paper by Leonard and Feirer.¹ These investigators assume no position in regard to the clinical importance of so called intestinal putrefaction. They do maintain, however, that true intestinal putrefaction is caused by the group of spore bearing anaerobes to which *Clostridium sporogenes* and *Clostridium putrificum* belong. As a result of tests on many normal subjects in which increasing dilutions of stools are added to tubes of Holman's cooked meat medium Leonard and Feirer conclude that the existence of any large numbers of putrefactive anaerobes in the intestine of human beings is comparatively rare. They treated twenty-eight subjects whose stools showed putrefactive anaerobes with Di-Hydranol over a period of from nineteen to twenty-nine days and observed the disappearance of *Clostridium sporogenes* and *Clostridium putrificum* from the feces. No return of the organisms occurred during a period of four months after treatment. These experiments although

not very extensive, do seem to warrant the conclusion of the authors that Di-Hydranol is effective in removing putrefactive anaerobes from the intestinal tract.

In regard to the clinical significance of these experiments, two questions must be raised.

1 Are the anaerobes *Clostridium sporogenes* and *Clostridium putrificum* solely responsible for the conditions called 'intestinal putrefaction,' 'chronic, intestinal toxemia' and 'auto-intoxication'?

2 Does putrefaction in the intestine have any clinical significance?

Leonard and Feirer apparently assume that the first question may be answered in the affirmative, but they give no references nor can any convincing evidence be found to support this position. Organisms of the colon-aerogenes group which are not affected by Di-Hydranol also produce ptomaine bases, amines, indole, skatole and phenol from the products of digestion in the intestine. A paper by Eustis⁴ describes the treatment of fourteen cases of obstinate intestinal toxemia with Di Hydranol over a period of from one to six months. This author used Salkowski's test for indicanuria (indole produced by the colon aerogenes group) as a guide to intestinal putrefaction. Improvement was noted in one of the cases but in the remaining thirteen cases no decrease in the indicanuria or evidences of clinical improvement were observed. This is the only direct clinical test of the value of Di-Hydranol in 'intestinal putrefaction' that can at present be found. Sharp & Dohme, Inc., state in the letter quoted that other investigations are now in progress but have not as yet been published.

The clinical importance of 'intestinal putrefaction' is at present and always has been a controversial subject, a fact admitted by Leonard and Feirer. The Council has held that the paper of Leonard and Feirer was insufficient to establish the clinical usefulness of Di-Hydranol.

Since the Council's last consideration of the drug, several papers have been written on the use of Di-Hydranol in the treatment of intestinal conditions other than "putrefaction." Leiva⁸ compared the effectiveness of Di-Hydranol with that of phenyl salicylate-methenamine in the treatment of cholera carriers and found that the two drugs were about equally effective. All but two of the seventy-two cases treated finally became negative most of them after from two to four days.

Favorable results have been reported by several investigators who used Di-Hydranol to treat intestinal protozoal infections in man and experimental animals.⁹ Most of the protozoa (including *Endamoeba histolytica* in carriers) were eliminated except those with resistant cyst capsules. *Endamoeba coli*, *Chilomastix* and *Giardia lamblia* were less amenable to the treatment. Faust points out that Di-Hydranol appears especially valuable for chronic carrier cases and for those in which hospitalization is not practical.

In the treatment of helminth infestations, Di-Hydranol seems to have little if any advantage over hexyl resorcinol.¹⁰ David and Johnstone in their paper quote two more investigators who report favorable results in the use of Di-Hydranol for intestinal protozoa and to a lesser extent for worms. The antihelminthic action of hexyl and heptyl resorcinols is greatly diminished when the drugs are given in olive oil; the best results being obtained with sugar coated or phenyl salicylate coated pills.

In conclusion it may be stated that Di-Hydranol appears to offer more promise in the treatment of infestations with intestinal parasites, especially protozoa, than it does for the treatment of that vague clinical condition 'intestinal putrefaction.' No further experimental evidence has been advanced by the manufacturer to justify the use of the drug in the latter condition other than that offered with the first presentation in 1931 and on this evidence the drug was found unacceptable.

The Council declared Di-Hydranol unacceptable for inclusion in New and Nonofficial Remedies because of lack of clinical evidence of its usefulness. This action was taken without prejudice against future reconsideration.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

NUEFUD

Manufacturer—Perewe Products Company, Brooklyn

Description—Small, noodle-like strips prepared from corn and potato starches and egg yolk

Manufacture—The potato and corn starches are sieved, mixed with liquid egg yolk until lumps are formed, kneaded to an elastic dough, rolled into sheets of one-sixteenth inch thickness, and thoroughly air dried. The dough sheets are shredded or cut into various forms, which are spread on canvas, dried at room temperature and packed into cartons

Analysis (submitted by manufacturer) —

	per cent
Moisture	12.5
Ash	1.3
Lipoids	26.0
Protein (N X 6.25)	12.5
Starch (diastase method)	47.5
Lipoid phosphoric acid (P O ₅)	0.66

Iron (Fe)	0.006
Magnesium (Mg)	0.01
Calcium (Ca)	0.05
Sodium (Na)	0.02
Potassium (K)	0.04

Calories—4.7 per gram 133 per ounce

Claims of Manufacturer—Rich in vitamins A and G, good source of vitamin B

GRIDDLE KING SELF-RISING PANCAKE FLOUR

Manufacturer—The Light Grain and Milling Company, Liberal, Kan

Description—A self-rising pancake flour containing winter wheat short patent flour, rye and corn flours, dextrose, calcium acid phosphate, sodium bicarbonate, salt, and dried skim milk

Manufacture—The ingredients are mixed in definite proportions in a batch mixer and automatically packed in fiber bags

Analysis (submitted by manufacturer) —

	per cent
Moisture	8.8
Ash	5.2
Fat (ether extraction method)	1.5
Protein (N X 5.7)	9.7
Reducing sugars as invert sugar	3.4

Calories—3.5 per gram 99 per ounce

JELL-O

A GELATIN DESSERT

(CHERRY, LEMON, LIME, ORANGE RASPBERRY AND STRAWBERRY FLAVORS)

Manufacturer—The Jell-O Company, Inc., LeRoy, N. Y., Division of General Foods Corporation

Description—Dessert powders containing cane sugar, gelatin, tartaric or citric acid, fruit flavor, and natural color

Manufacture—The ingredients in definite proportions are mixed and automatically packed

Analysis (submitted by manufacturer) —

	per cent
Moisture	0.8
Ash	0.2
Protein (N X 5.55)	11.0
Sucrose	86.0
Tartaric or citric acid	2.0

Calories—3.9 per gram 111 per ounce

JELKE GOOD LUCK SHORTENING

Manufacturer—John F. Jelke Company, Chicago

Description—Mixture of oleo oil and cottonseed oil

Manufacture—The two oils are thoroughly mixed in a steam jacketed tank, solidified and printed into pound blocks

Analysis (submitted by manufacturer) —

	per cent
Fat (ether extract)	100
Protein (N X 6.25)	0.03
Ash	0.004

GOLD CHAIN WHOLE WHEAT FLOUR

RED CHAIN WHOLE WHEAT FLOUR

Manufacturer—Universal Mills, Fort Worth, Texas

Description—Hard dark whole wheat flour

Manufacture—Whole wheat is cleaned, scoured, crushed and ground by the usual milling procedure. It is packed in packages for home use and sacks for commercial use

Analysis (submitted by manufacturer) —

	per cent
Moisture	12.13
Ash	1.8
Fat (ether extraction method)	2.0
Protein (N X 5.7)	16.0
Reducing sugars as invert sugar	2.0
Crude fiber	1.8
Carbohydrates other than crude fiber (by difference)	65.9

Calories—3.5 per gram 99 per ounce

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard

JELKE GOOD LUCK SANDWICH SPREAD

Manufacturer—John F. Jelke Company, Chicago

Description—Sandwich spread containing water, cottonseed (or corn) oil, sweet pickle relish, sucrose, distilled vinegar, corn starch, salt, eggs, tapioca flour and mustard

Manufacture—The ingredients in definite proportions are prepared and admired as described for Jelke Good Luck Salad Dressing (THE JOURNAL, May 5 1934, p. 1472)

Analysis (submitted by manufacturer) —

	per cent
Moisture	42.7
Total ash	3.7

Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	18.3
Titrate acidity as acetic acid	1.1
Lipoid phosphoric acid as P O ₅	0.027
Total phosphoric acid as P O ₅	0.029

Calories—3.8 per gram 108 per ounce

PLEE-ZING UNSWEETENED COOKING CHOCOLATE

Distributor—Plee-Zing, Inc., Chicago

Manufacturer—Moffat, Inc., Boston

Description—Ground cacao nibs or "chocolate liquor" in cake form. Same as Moffat Cooking Chocolate Unsweetened, THE JOURNAL, Jan. 20 1934, page 213

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard

OCCIDENT FLOUR

(BLEACHED OR UNBLEACHED)

Manufacturer—Russell Miller Milling Company, Minneapolis

Description—Hard wheat short patent flour, bleached or unbleached

Manufacture—Selected hard wheat is cleaned, washed, tempered and milled by essentially the same procedures as described in THE JOURNAL June 18, 1932 page 2210. Chosen flour streams are blended and bleached with nitrogen oxide and benzoyl peroxide or nitrogen trichloride

THE CLEVELAND SESSION

AMERICAN MEDICAL ASSOCIATION, EIGHTY-FIFTH ANNUAL SESSION
CLEVELAND, OHIO, JUNE 11-15, 1934

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The eighty-fifth annual session of the American Medical Association will be held in Cleveland, June 11-15, 1934

The House of Delegates will convene at 10 a m, Monday, June 11 In the House the representation of the various constituent associations for 1932 1933 and 1934 is as follows

Alabama	3	New Hampshire	1
Arizona	1	New Jersey	4
Arkansas	2	New Mexico	4
California	7	New York	17
Colorado	2	North Carolina	3
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	3
Florida	2	Oregon	1
Georgia	3	Pennsylvania	10
Idaho	1	Rhode Island	1
Illinois	10	South Carolina	2
Indiana	4	South Dakota	1
Iowa	3	Tennessee	3
Kansas	2	Texas	5
Kentucky	3	Utah	1
Louisiana	2	Vermont	1
Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	6	West Virginia	2
Michigan	5	Wisconsin	3
Minnesota	3	Wyoming	1
Mississippi	2	Alaska	1
Missouri	5	Hawaii	1
Montana	1	Isthmian Canal Zone	1
Nebraska	2	Philippine Islands	1
Nevada	1	Puerto Rico	1

The fifteen scientific sections of the American Medical Association, the Medical Corps of the Army the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each

The Scientific Assembly of the Association will open with the general meeting to be held at 8 p m, Tuesday, June 12 The sections will meet Wednesday, Thursday and Friday, June 13, 14 and 15 as follows

CONVENING AT 9 A M THE SECTIONS ON

Surgery, General and Abdominal	Nervous and Mental Diseases
Ophthalmology	Dermatology and Syphilology
Pediatrics	Gastro-Enterology and Proctology
Pharmacology and Therapeutics	Radiology

CONVENING AT 2 P M, THE SECTIONS ON

Practice of Medicine	Pathology and Physiology
Obstetrics Gynecology and Abdominal Surgery	Preventive and Industrial Medicine and Public Health
Laryngology Otology and Rhinology	Urology
Miscellaneous Topics	Orthopedic Surgery
Session on Forensic Medicine	
Session on Nutrition	

The Registration Department will be open from 8 30 a m until 5 30 p m Monday Tuesday Wednesday and Thursday June 11 12 13 and 14 and from 8 30 a m to 12 noon, Friday, June 15

DEAN LEWIS President
F C WARSHUIS, Speaker House of Delegates
OLIN WEST, Secretary

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included

CLEVELAND—THE CONVENTION CITY

Cleveland was a trading post on the Western Reserve frontier when Moses Cleaveland laid out the Public Square in 1796. Today it is the home of a million and a quarter people. The Public Square, which has always been the hub of its activities, was purchased by the Connecticut Land Company for \$175 in 1795. Today, a reasonable sale price would be \$20,000,000. Situated at the crossroads between the Atlantic States and the Middle West and founded by New Englanders, Cleveland has an atmosphere that places it somewhere between conservative New England and the breezier Middle West. Some of the smaller towns in the Western Reserve might easily be mistaken for New England villages, on casual inspection. Although numerically the sixth city in the United States, Cleveland has many of the comfortable attributes of the small town.

When the first cargo of iron ore from the Lake Superior region entered Cleveland's harbor in 1852, the immense lake traffic which is an important factor in the city's industrial life today was born. Visitors invariably find great fascination in the expanse of lake front with its busy wharves and ore docks, and the tug-escorted ore boats wending their tortuous way through the winding Cuyahoga River to the steel mills beyond.

Iron and steel have been Cleveland's premier industries since 1828, when the first smelter was established, and her present capacity is now over three million tons of pig iron annually. The industry now boasts continuous rolling mill equipment that is not equaled anywhere else in the world. The city also leads the world in production of wire nails, bolts and screws, malleable castings and heavy machinery and is one of the nation's largest hardware centers. Other leading Cleveland industries are multigraph and sewing machine manufacture, production of automotive bodies and parts, paints and varnish, ready-made clothing and knit goods, electrical machinery and apparatus, brick and tile. Ten thousand persons annually visit Nela Park to inspect the exhibits and demonstrations in this home of the National Lamp Works of the General Electric Company.

The branch banking system has reached its greatest development in Cleveland, and one of its banks has more depositors

than any other bank in any other American city. Cleveland's stores offer rarely excelled shopping opportunities. Euclid Avenue is one of the world's most famous shopping streets. One of its great stores sells more than \$50,000,000 worth of merchandise annually and is paid for it.

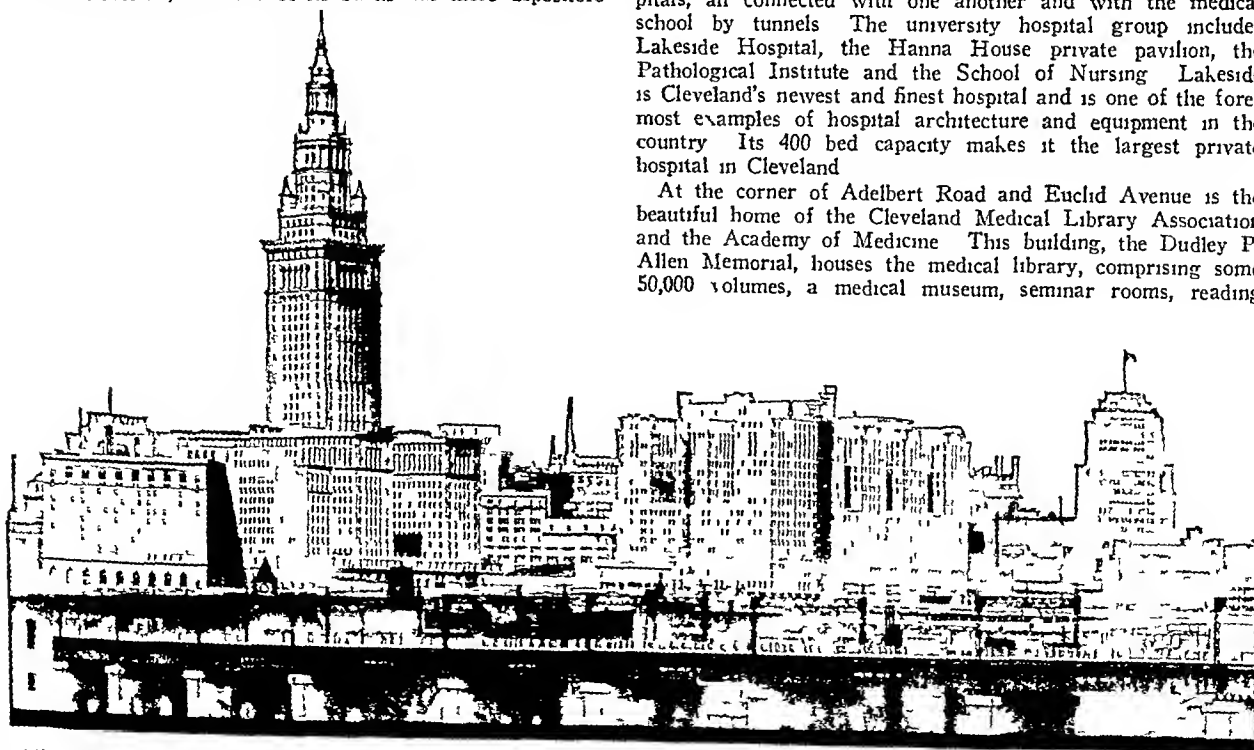

Two of Cleveland's noteworthy achievements in recent years are the development of the Mall, which extends from the lake front into the heart of the business district, and the completion of the mammoth Terminal group of buildings, which is a city within itself. The Mall, which is a huge T of 168 acres, will ultimately represent an investment of \$40,000,000 and includes the Federal Building, the Public Library, the Board of Education Building, the Public Auditorium, City Hall, the Cuyahoga County Court House, and the new municipal stadium on the lake.

The Public Hall, where all the meetings of the annual session will be held, is perhaps the most complete and serviceable municipal auditorium in the country. The huge main auditorium seats 12,500, while the Music Hall seats 3,000. As these two auditoriums have a common stage, 16,000 persons can be seated for a single event. The Ball Room and Little Theater have seating capacities of 1,500 and 700, respectively, and ten other halls range in seating capacity from 90 to 500. The Hall contains 200,000 square feet for exhibition purposes and every modern exhibit facility. It is located in the heart of the downtown district within easy walking distance of the principal hotels.

MEDICAL CLEVELAND

The School of Medicine of Western Reserve University and its affiliated hospitals form an important unit of medical Cleveland. The physical plant of the medical school is a modern five-story limestone building completed in 1924, the gift of the late Samuel Mather. It is located on a court off Adelbert Road near the campus of Adelbert College of Western Reserve University. Directly opposite the school are Babies and Childrens and Maternity hospitals, while several hundred yards to the north are the handsome buildings of the University Hospitals, all connected with one another and with the medical school by tunnels. The university hospital group includes Lakeside Hospital, the Hanna House private pavilion, the Pathological Institute and the School of Nursing. Lakeside is Cleveland's newest and finest hospital and is one of the foremost examples of hospital architecture and equipment in the country. Its 400 bed capacity makes it the largest private hospital in Cleveland.

At the corner of Adelbert Road and Euclid Avenue is the beautiful home of the Cleveland Medical Library Association and the Academy of Medicine. This building, the Dudley P. Allen Memorial, houses the medical library, comprising some 50,000 volumes, a medical museum, seminar rooms, reading

THE TERMINAL TOWER GROUP INCLUDING THE TERMINAL TOWER BUILDING THE HOTEL CLEVELAND THE MEDICAL ARTS BUILDING THE BUILDERS' EXCHANGE THE MIDLAND BANK A LARGE DEPARTMENT STORE AND RAILWAY TERMINAL FACILITIES THE BELL TELEPHONE BUILDING IS AT THE EXTREME RIGHT

rooms, offices, executive offices of the Academy of Medicine and an auditorium seating 550. A short distance south of the medical group is the School of Dentistry, while surrounding it are the campus and various academic departments of the university and the Case School of Applied Sciences.

Within a stone's throw of the Medical Center are Severance Hall, the beautiful home of the Cleveland Orchestra, and the Museum of Art, with the Fine Arts Garden and Lagoons stretching before them. The Western Reserve Historical Museum and the School of Education are located on University Circle, a short distance from the Medical Center. The Museum of Natural History is located on Euclid Avenue farther in town.

The university district lies about three and a half miles east of Public Square, and only a short distance from the main uptown business district at Euclid Avenue and East One Hundred and Fifth Street. A quarter of a mile north of this district is Mount Sinai Hospital, Cleveland's third largest private hospital. Just below Mount Sinai Hospital, the broad expanse of Rockefeller Park winds its way northward to Lake

general wards for medical, surgical, pediatric and dermatologic patients, the Psychopathic Division, the Contagious Hospitals, the Pathological Laboratories, and the new Lowman Pavilion for Tuberculous Patients. The psychopathic and tuberculosis divisions serve as clearing houses for the acute cases coming within their specialties. After study, many of these patients are then transferred to appropriate city, county or state institutions for further care.

Aside from the municipal institution, Cleveland's hospitals and welfare activities are coordinated by the Welfare Federation, which has been faithfully administered for the past fifteen years by public spirited citizens. The community fund idea found its inception and greatest development in Cleveland. Through this agency millions of dollars have been subscribed annually for the hospitals and welfare activities of the community. The Welfare Federation supervises the budgeting and division of funds among the various agencies. The Hospital Council is a subsidiary organization which aids the participating hospitals in their common financial relations and in settling mutual administrative problems.

THE CLEVELAND PUBLIC AUDITORIUM
Headquarters of Annual Meeting of American Medical Association

Eric Women's Hospital also occupies this district. Half a mile to the west are the buildings of the Cleveland Clinic, which include a new clinic building, the hospital and the laboratories of the Clinic Research Foundation. The Cleveland Clinic, organized by Dr. George W. Crile and his associates ten years ago, is one of the largest and best known private clinics in the country.

CLEVELAND HOSPITALS

In addition to Lakeside and affiliated hospitals, medical students receive clinical instruction in Charity and City hospitals. Charity Hospital, which is one of Cleveland's pioneer institutions, remains as the only hospital in downtown Cleveland. It is located on East Twenty-Second Street four blocks south of Euclid Avenue. Charity Hospital has contributed greatly to the medical history of the community. It has a capacity of 300 beds. Within recent years, Lakeside, U. S. Marine, Huron Road and St. Luke's hospitals have left the downtown section for less crowded quarters in the outlying districts on the east side.

The department of welfare of the city of Cleveland has as its director David S. Ingalls, former assistant secretary of the navy. Under his direction are the various public health activities of the municipality, including the department of health, City Hospital, the City Correction Farm at Warrensville and Sunny Acres Tuberculosis Sanitarium. City Hospital houses 1,600 patients. The units included within its walls are the

St. Luke's Hospital, affiliated with the Methodist Episcopal Church, occupies a monumental plant of recent completion on Shaker Boulevard, near the edge of Shaker Heights, in the southeastern part of the city. Its 390 bed capacity makes it the second largest private hospital.

St. Alexis Hospital, with its 220 bed capacity, is located in the steel mill district on the south side. It is one of the city's oldest hospitals. St. Alexis, Charity, St. John's and St. Ann's Maternity Hospital are the major Catholic hospitals of the community. St. John's Hospital is located on Detroit Avenue on the west side, and has 207 beds, while St. Ann's Maternity is located on lower Woodland Avenue.

Among the other community fund hospitals are Lutheran and Fairview hospitals on the west side, Grace Hospital on the southwest, Evangelical Deaconess in Brooklyn, and Glenville Hospital in the northeastern part of the city. Rainbow Hospital, located in South Euclid, affiliated with the university, is a 125 bed convalescent hospital for chronic orthopedic and medical conditions among children. Huron Road Hospital has a new home nearing completion in East Cleveland.

THE ACADEMY OF MEDICINE

The Academy of Medicine of Cleveland is fortunate in having its own plant in conjunction with the Cleveland Medical Library. All its administrative offices and meeting rooms are located here. The scientific activities of the Academy include monthly general meetings and monthly or quarterly meetings.

In addition to the usual organization committees, the Academy has an active economics committee, which is studying many pressing economic problems, making contacts with similar committees throughout the country, and advising the membership concerning problems studied. The Health Education Committee sponsors a series of educational lectures to the public annually and has sponsored radio programs. A committee on postgraduate study has presented courses on diseases of the respiratory tract and diseases of the gastro-intestinal tract, which have been well attended by the membership during the past two years. Special clinical demonstrations of latest methods of immunization were given the members prior to the preschool roundup last summer. A course on obstetrics and gynecology has been projected for next year.

The Academy has a full time executive office, a twenty-four hour call bureau service for members and information service for the public, and publishes a monthly bulletin. The Academy is responsible for developing the Cleveland Dispensary Admissions Plan, which has been widely copied elsewhere and which has been instrumental in maintaining in private practice thousands of patients who would otherwise have become dispensary clients. The Academy also put in effect a plan for rating patients of the "white collar class" and placing at their disposal a lower cost consultation service.

CLEVELAND AS A SUMMER RESORT

Lake Erie breezes help to maintain a comfortable temperature in Cleveland throughout practically the entire summer. This fact, together with the unequalled facilities for outdoor rest and recreation, make the city and surrounding country an ideal summer resort. The lake shore for many miles is dotted with summer colonies and several excellent amusement parks. Lake Erie provides admirable swimming, sailing, speed boating and fishing. Numerous day or overnight trips on the large lake steamers are available. In addition, there are numerous small lakes within a radius of fifty miles of the city which provide excellent swimming, boating and fishing, and several well stocked streams to tempt the angler. The district abounds in golf courses, some of them with as fine layouts as are to be found anywhere in the country. Many excellent clay courts are available for devotees of tennis. The Metropolitan Park system and city parks include miles of parkways and beauty spots for exploration on foot, horseback or motor. Many excellent stables and bridle paths which wind through the entire Cleveland district promise the horseman many hours of pleasant exploration. Hundreds of miles of excellent highways take the motorist through beautiful valleys, over hilly country or along the lake shore, and inns that provide excellent meals and comfortable lodging dot the countryside. In the city, theaters, night clubs and restaurants abound.

Cleveland is easily reached by water, rail, air and highway, being located on the main routes of all methods of travel, as is described in the item which follows.

TRANSPORTATION

Railroad Rates to Cleveland

Special rates have been granted for the benefit of members of the American Medical Association and dependent members of their families who will attend the annual session at Cleveland.

The Central, the New England, the Southwestern, the Transcontinental and the Western Passenger Associations as well as the Eastern Lines of the Canadian Passenger Association, have granted a rate of one and one-third fares. This rate is granted also by the Western Lines of the Canadian Passenger Association from Winnipeg and certain points in British Columbia.

To have the benefit of a return rate of one-third fare it will be necessary for each member to secure a **CERTIFICATE** from the railroad ticket agent when he purchases his ticket to Cleveland. The certificate must be certified to by the Secretary of the American Medical Association, which may be done at the registration Bureau, to be located in the Cleveland Public Auditorium, and must then be validated by a representative of the railroads. When the certificate is so certified and validated, it will entitle its holder to purchase a return ticket to his home, over the same route traveled to Cleveland, at one-third fare.

If the ticket agent at the member's home station does not have the certificate, he will furnish information as to where it may be obtained.

The certificate is not a receipt for money paid for a ticket, nor will a receipt entitle its holder to secure a return trip ticket at a reduced rate. Be sure to ask the ticket agent for a **CERTIFICATE**.

The dates of sale of tickets to Cleveland will be June 5 to 13 in the territory of the Eastern Lines of the Canadian Passenger Association as well as in the territories of the Central Passenger Association, the New England Passenger Association, the Transcontinental Passenger Association and the Western Passenger Association, and from Arkansas, Kansas, Louisiana,

Missouri, as well as Natchez, Miss., and Memphis, Tenn., in the territory of the Southwestern Passenger Association. The dates of sale of tickets from Oklahoma and Texas in the territory of the Southwestern Passenger Association will be June 4 to 12.

Certificates properly certified and validated will be honored for purchasing tickets for the return journey at one third fare up to and including June 19. No refund of fare will be made on account of failure to present validated certificate when purchasing return ticket. The return ticket must be used over the same route as that traveled going to Cleveland.

When you purchase your ticket to Cleveland, secure from the railroad ticket agent a **CERTIFICATE**, which, when properly certified to and validated will entitle you to purchase a return ticket to your home over the same route traveled to Cleveland, at one-third the fare paid for your ticket to Cleveland.

BE SURE TO ASK YOUR RAILROAD TICKET AGENT FOR A CERTIFICATE WHEN PURCHASING YOUR TICKET TO CLEVELAND

Summer Excursion Fares

Summer excursion fares in the territories of the Transcontinental and Western Passenger Associations, which are on a lower basis than convention fares, will apply from the following territory: Arizona, British Columbia, California, Colorado (except Julesburg), Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming.

Boat Transportation Between Cleveland and Buffalo

The Cleveland and Buffalo Transit Company has announced that round trip rail tickets in either direction optionally provide rail or lake travel between Cleveland and Buffalo. Detailed information may be secured from the Cleveland and Buffalo Transit Company, Cleveland, Ohio.

THE CLEVELAND PUBLIC LIBRARY

REGISTRATION

The Bureau of Registration will be located in the Cleveland Public Auditorium, Lakeside Avenue at East Sixth Street. Members of the Committee on Registration of the Local Committee on Arrangements will be on hand to assist those who desire to register. A branch postoffice in charge of government postoffice officials will be available for visitors and an information bureau will be operated in connection with the Bureau of Registration.

Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows, and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have, on the prescribed form, applied for Fellowship, subscribed to THE JOURNAL, and paid their Fellowship dues for the current year. The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues, and these cards should be presented at the registration window. Any who have not received cards for 1934 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago.

Members in Good Standing Eligible to Fellowship

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order that pocket cards may be secured and brought to Cleveland so that registration can be more easily and more promptly effected. Application forms may be had on request. Subscribers to THE JOURNAL who have not received pocket cards for 1934 should write to the American Medical Association for application blanks and information as to further requirements.

Register Early

Fellows living in Cleveland, as well as all other Fellows who are in Cleveland on Monday and Tuesday, should register as early as possible. The names of those who register will appear in the *Daily Bulletin* the next day, and this will enable visiting physicians to find friends if they have registered.

Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card, which will be found on the tables in front of the Registration Bureau. Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card, and sign the application on the back. These cards will be found on the tables. Entries on the registration cards should be written plainly, or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin*, published on Tuesday, Wednesday, Thursday and Friday of the week of the session. Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card, together with their pocket cards, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session.

As previously stated, it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than May 21. Any applications received later than May 21 will be given prompt attention, but the Fellowship pocket card may not reach the applicant in time for him to register at the Cleveland session.

It will be possible for members of the organization to qualify as Fellows at Cleveland. In order to do this, applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. As already stated, registration can be effected more easily and more promptly if members qualify as Fellows before leaving home.

It is suggested that those who apply for Fellowship at Cleveland provide themselves, before leaving home, with certificates signed by the secretaries of their state associations, attesting that they are members in good standing in state and county branches of the organization. A state membership card for 1934 will be acceptable. The certificate or membership card should be presented along with the filled in *blue* registration card at the window in the booth marked "Applicants for Fellowship and Invited Guests."

Registration for Delegates at the Hotel Statler

General Officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly at a booth near the Ball Room of the Hotel Statler. This arrangement is made for the convenience of the members of the House of Delegates, which will convene on Monday morning at 10 o'clock in the Ball Room of the Hotel Statler. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock, Monday morning, June 11, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

CLEVELAND HOTELS

A list of Cleveland hotels is presented for the benefit of those who expect to attend the annual session of the American Medical Association, June 11-15. Dr. Hubert C. King is the chairman of the Subcommittee on Hotels of the Local Committee on Arrangements and may be addressed at 1604 Terminal Tower, Cleveland, Ohio. The advertising announcement and coupon for reservations appear on advertising page 95 of this issue.

ENTERTAINMENT

The Ohio State Medical Association and the Academy of Medicine of Cleveland are hosts to the convention and will maintain permanent information desks in the North Lobby of the Public Hall and the Lobby of the Hotel Carter, which is the headquarters for Women's Entertainment.

The Academy of Medicine will publish a special issue of its Bulletin for distribution to all members of the American Medical Association who register. It will contain a list of the entertainment features, together with descriptive material about points of interest in Cleveland and vicinity.

ner, which is sponsored by the Women's Entertainment Committee of the Academy of Medicine and the Woman's Auxiliary of the American Medical Association, will take place prior to the President's Reception and Ball. Members attending the convention who are not accompanied by their wives are also urged to attend.

Medical Women's National Association

The Medical Women's National Association will hold its annual meeting in the Hotel Cleveland, June 10-12. Sessions

Above—SEVERANCE HALL THE HOME OF THE CLEVELAND ORCHESTRA

Opening General Meeting

The Opening General Meeting will take place on Tuesday evening, June 12, at 8 o'clock, in the Music Hall, Cleveland Public Auditorium.

President's Reception

The President of the American Medical Association will be honored with a reception and ball to be held Thursday evening, June 14, at 9 o'clock, in the ballroom of the Hotel Cleveland.

Dinner for General Officers and Delegates

The Ohio State Medical Association and the Academy of Medicine of Cleveland will be joint hosts on Monday evening, June 11 at 6 30, in the Union Club, where they will entertain the general officers and members of the House of Delegates of the American Medical Association with a dinner.

Medical Veterans

The Medical Veterans of the World War will be the guests of the Cleveland medical veterans on Wednesday evening, June 13, when they will be entertained with a smoker and buffet luncheon at Hotel Statler. A program of informal talks is being arranged.

"Bring-Your-Husband" Dinner

On Thursday evening, June 14 the annual "Bring-Your-Husband-Dinner" will be held at the Hotel Carter. This dinner

will open Sunday afternoon at 2 o'clock and close with the annual banquet on Tuesday, June 12, at 6 30 p. m.

Breakfast meetings will be held during the week at Hotel Cleveland.

Alumni Dinners

Notice has been received of the following alumni dinners to be held during the week of the convention:

University of Toronto, Wednesday, June 13, 6 30 p. m., Hotel Carter.

University of Minnesota, Wednesday, June 13, 6 00 p. m., Hotel Carter.

University of Pennsylvania, Wednesday, June 13, 6 30 p. m., Hotel Carter.

Western Reserve University, Wednesday, June 13, 6 30 p. m., Hotel Carter.

Creighton University, Wednesday, June 13, 6 30 p. m., Hotel Statler.

Missouri Medical College, Tuesday, June 12, 6 30 p. m., Hotel Statler.

St. Louis University School of Medicine, Wednesday, June 13, 6 30 p. m., Hotel Statler.

Rush Medical College, Wednesday, June 13, 6 30 p. m., Hotel Statler.

Johns Hopkins Medical School, Wednesday, June 13.

Dates in some cases are tentative and further information should be sought at the Academy of Medicine Information Desk at Public Hall.

Fraternity and Club Luncheons

The Alpha Kappa Kappa Fraternity will have its luncheon at the Hotel Hollenden, Wednesday, June 13, at 12 30 p m. The Alpha Mu Pi Omega fraternity luncheon will be held at the Hotel Cleveland, Wednesday noon, June 13.

Alumni of Phi Rho Sigma fraternity will meet for luncheon at 12 30 p m, Wednesday, June 13, in the Showboat Room of the Hotel Hollenden. On the mornings of June 11, 12 and 13 the visiting Phi Rhos may register and secure information at a desk on the mezzanine floor of the Hotel Statler.

The Phi Delta Epsilon medical fraternity will hold a luncheon for its members who will attend the annual session in Cleveland in the Showboat Room of the Hollenden Hotel, Thursday noon.

Visiting members of the various national luncheon clubs will be welcome at the luncheons of the local clubs as follows: Kiwanis Club Hotel Cleveland, Thursday noon, June 14; Rotary Club Hotel Statler Thursday noon June 14; Lions Club Hotel Carter, Thursday noon, June 14.

Program for Entertainment of Women Guests

HEADQUARTERS, HOTEL CARTER

GOLF TOURNAMENT

The American Medical Golfing Association will hold its twentieth annual tournament at the Mayfield Country Club in Cleveland on Monday, June 11.

Thirty-six holes of golf will be played in competition for the fifty trophies and prizes in the eight events. The trophies include the Association Championship for thirty-six holes gross, the Association Handicap Championship for thirty-six holes net, the Choice Score Handicap Championship for thirty-six holes gross, the low gross Eighteen Hole Championship, the low net Eighteen Hole Handicap Championship, the Maturity Event limited to Fellows over 60 years of age, the Oldguard Championship limited to competition of past presidents, and the Kickers Handicap. The championship event has as its

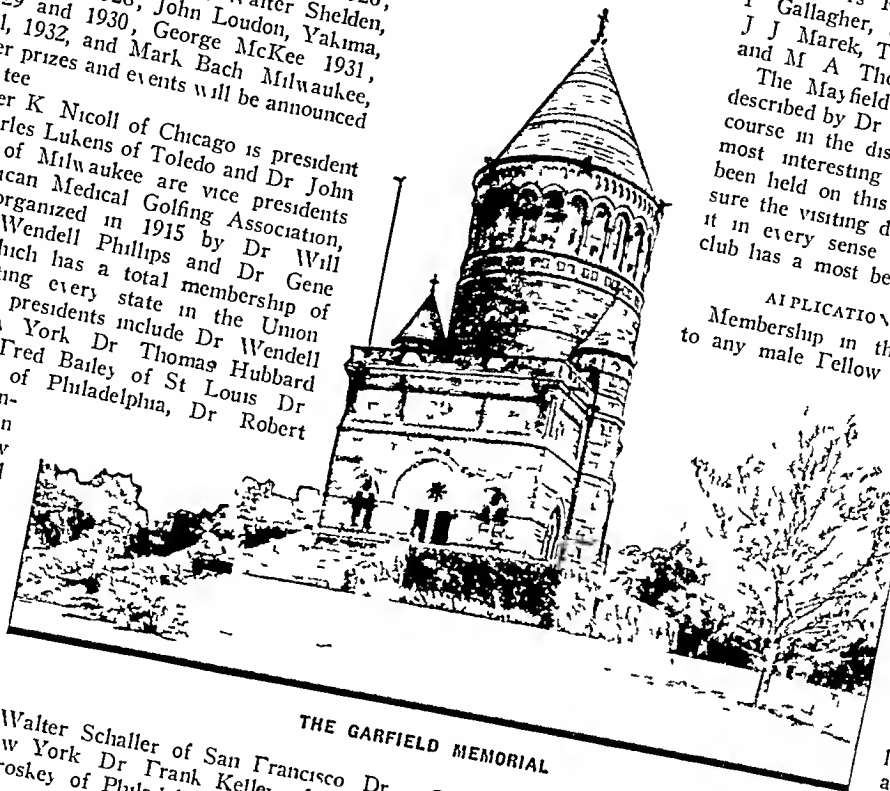

major prize the famous Will Walter Trophy, awarded since 1923 for low gross thirty-six holes. This trophy, designed by Edgar Millar and executed by the Cellini Shop, Evanston, Ill., symbolizes the evolution of medicine. The first handle depicts the age of primitive ignorance, with shaman witch doctor, spells and the invocation of nature gods to cure ailing mankind, from antiquity to 500 B C. The second handle shows the age of Greek thinkers, bearing the serpents symbolic of Aesculapius god of medicine—an age of thought and research, from 500 B C to 640 A D. The third handle represents the age of medieval superstition from 640 A D to 1500 A D with an astrologer, the physician common to the dark ages. The fire of incantation rises behind the figure as he traces a cabalistic sign in the air.

THE PROGRAMS OF THE SECTIONS

JOUR A M A
MAY 12 1934

The fourth handle depicts the age of modern medical research from the Renaissance to modern time, with increasing light spreading from a figure symbolic of an enlarging vision. Winners since the cup was placed in competition have been Drs E A Seaforth, San Francisco, 1923, George McKee, Pittsburgh, 1924, Homer Nicoll, Chicago, 1925, S M Hill, Dallas Texas, 1926, George McKee again in 1927, Walter Shelden, Rochester, Minn., 1928, John Loudon, Yakima, Wash., 1929 and 1930, George McKee 1931, S M Hill, 1932, and Mark Bach Milwaukee, 1933. Other prizes and events will be announced at the first tee.

Dr Homer K Nicoll of Chicago is president and Dr Charles Lukens of Toledo and Dr John W Powers of Milwaukee are vice presidents of the American Medical Golfing Association, which was organized in 1915 by Dr Will Walter, Dr Wendell Phillips and Dr Gene Lewis, and which has a total membership of 1,100 representing every state in the Union. The living past presidents include Dr Wendell Phillips of New York, Dr Thomas Hubbard of Toledo, Dr Fred Bailey of St Louis, Dr Edward Martin of Philadelphia, Dr Robert Moss of San Antonio, Dr Charlton Wallace of New York, Dr Will Walter of Charlottesville, Va., Dr James Eaves of San Francisco, Dr D Chester Brown of Danbury Conn., Dr Samuel Childs of Denver, Dr W D Shelden of Rochester Minn, Dr Walter Schaller of San Francisco, Dr Edwin Zabriskie of New York, Dr Frank Kelley of Detroit and Dr John Welsh Croskey of Philadelphia.

THE GARFIELD MEMORIAL

The Cleveland committee is under the chairmanship of Dr John B Morgan 1301 Medical Arts Building, Cleveland, Ohio. He will be assisted by Drs R H Birge, A V Boysen, E F Gallagher, Second Large, E P McNamee, J J Marek, Theodore Miller, U V Portmann, and M A Thomas.

The Mayfield Country Club of Cleveland is described by Dr Morgan as probably the finest course in the district, and certainly one of the most interesting. Many championships have been held on this course," he says "and I am sure the visiting doctors will be delighted with it in every sense of the word. This country club has a most beautiful club house."

APPLICATION FOR MEMBERSHIP
Membership in the A M G A is open to any male Fellow of the American Medical Association. Write the Executive Secretary, William J Burns, 4421 Woodward Avenue, Detroit, for an application blank. Participants in the A M G A tournament are required to furnish their home club handicap signed by the secretary. No handicap over 25 is allowed.

The twentieth tournament of the American Medical Association will be a gay affair, attended by some two hundred medical golfers from all parts of the United States.

Femoral Hernia Operative Repair by Fascial Suture (Lantern Demonstration) R L PAINE, Norfolk, Va
Discussion to be opened by H W CAVE, New York, and F W BAILEY, St Louis
Contusions of the Heart (Lantern Demonstration) CLAUDE S BECK, Cleveland
Discussion to be opened by R L SANDERS Memphis, Tenn, and JOSEPH T WEARN, Cleveland
Surgical Treatment of Extensive Malignant Lesions of the Stomach (Lantern Demonstration) WALTER W WALTERS, Rochester, Minn
Discussion to be opened by FRANK H LAHEY, Boston, and GATEWOOD, Chicago
The Treatment of Perforated "Peptic" Ulcers HUGH H TROUT, Roanoke, Va
Discussion to be opened by ROY D MCCLURE, Detroit, and EDWARD J DONOVAN, New York
The Recognition and Treatment of Jejunal Ulceration (Lantern Demonstration) ROSCOE R GRAHAM, Toronto, Canada
Discussion to be opened by DEAN LEWIS Baltimore, and DONALD C BALFOUR, Rochester, Minn
The Surgical Treatment of Carcinoma of the Lungs and Bronchi (Lantern Demonstration) WILLIAM F RIENHOFF JR, Baltimore
Discussion to be opened by EVARTS A GRAHAM, St Louis, and CARL A HEDBLOM, Chicago

Thursday, June 14—9 a m

Chairman's Address Lung Abscess (Lantern Demonstration) HAROLD BRUNN San Francisco
The Bearing of Certain Physiologic Facts on Gastro-Intestinal Surgery (Lantern Demonstration) J SHELTON HORSLEY, Richmond, Va
Discussion to be opened by FRANK K BOLAND, Atlanta, Ga, and GEORGE W CRILE, Cleveland
The Management of Perforated Appendicitis JOHN F GILE and JOHN P BOWLER, Hanover, N H
Treatment of Appendicitis Associated with Peritonitis (Lantern Demonstration) FRED A COLLIER, Ann Arbor, Mich
Discussion on papers of DRS GILE and BOWLER and DR COLLIER to be opened by E STARR JUDD, Rochester Minn ALTON OCHSNER New Orleans, and LE GRAND GUERRY, Columbia, S C
Diagnosis and Treatment of Tumors of the Breast Clinically Benign and Clinically Malignant as Based on Biopsy (Lantern Demonstration) J C Bloodgood Baltimore
Discussion to be opened by IRVIN ABELL, Louisville, Ky, and MAX CUTLER, Chicago
Intestinal Rectal and Bladder Complication Resulting from Prolonged Radium and X-Ray Irradiation for Malignant Conditions of the Pelvis Surgical Treatment THOMAS E JONES Cleveland
Discussion to be opened by FLOYD E KEENE, Philadelphia, and GEORGE G WARD, New York

Friday, June 15—9 a m

Election of Officers
Alterations of Function in Biliary Tract Disease (Lantern Demonstration) I S RAVDIN and C G JOHNSTON, Philadelphia
Physiologic Principles to Be Considered in the Therapy of Biliary Tract Disease The Physiology of the Gallbladder, Some Principles to Be Considered in Therapy (Lantern Demonstration) A C IVI, Chicago
A Consideration of the Stoneless Gallbladder EVARTS A GRAHAM, St Louis
Discussion on papers of DRS RAVDIN and JOHNSTON, IVI and GRAHAM to be opened by URBAN MAES New Orleans, and WALTER W WALTERS, Rochester, Minn
Carcinoma of Cecum What Are the Chances for Cure (Lantern and Motion Picture Demonstration)? C F DIXON, Rochester, Minn
Discussion to be opened by JEROME M LYNCH New York and T M JOYCE Portland, Ore
Surgical Treatment of Ulcerative Colitis (Lantern Demonstration) R B CATTELL Boston
Discussion to be opened by F R PETERSON Iowa City, and ALFRED A STRAUSS Chicago

Present Status of Tetanus, with Special Regard to Treatment
(Lantern Demonstration)

RICHARD H. MILLER and HORATIO ROGERS, Boston
Discussion to be opened by J. M. Wainwright, Scranton,
Pa., and D. B. Pfeiffer, Philadelphia

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

MEETS IN MUSIC HALL, ARENA FLOOR, CLEVELAND
PUBLIC AUDITORIUM

OFFICERS OF SECTION

Chairman—JOSEPH B. DE LEE, Chicago
Vice Chairman—PAUL TITUS, Pittsburgh
Secretary—JAMES R. McCORD, Atlanta, Ga.
Executive Committee—FRED L. ADAIR, Chicago; BARTON
COOKE HIRST, Philadelphia; JOSEPH B. DE LEE, Chicago

Wednesday, June 13—2 p. m.

SYMPOSIUM ON MODERN INDICATIONS FOR THERAPEUTIC ABORTION

Neuropsychiatry CLARENCE O. CHENEY, New York
Ophthalmology (Lantern Demonstration)

HENRY P. WAGENER, Rochester, Minn.

Cardiology HAROLD E. B. PARDEE, New York

Nephrology (Lantern Demonstration)

W. W. HERRICK, New York

Pulmonology (Lantern Demonstration)

F. M. POTTINGER, Monrovia, Calif.

Discussion on paper of DR. CHENEY to be opened by
H. DOUGLAS SINGER, Chicago, on paper of DR.
WAGENER by ARTHUR J. BEDELL, Albany, N. Y.
on paper of DR. PARDEE by BURTON E. HAMILTON,
Boston, on paper of DR. HERRICK by ROBERT D.
MUSSEY, Rochester, Minn., and on paper of DR.
POTTINGER by FRED L. ADAIR, Chicago. General
discussion to be opened by FREDERICK J. TAUSSIG,
St. Louis.

Thursday, June 14—2 p. m.

The Advantages of Paraldehyde as a Basic Amnesic Agent
in Obstetrics (Lantern Demonstration)

R. A. BARTHOLOMEW, Atlanta, Ga.

Discussion to be opened by HAROLD H. ROSENFELD,
Boston.

Practical Measures in the Prevention and Treatment of
Puerperal Sepsis (Lantern Demonstration)

B. P. WATSON, New York.

Discussion to be opened by J. C. LITZENBERG, Minne-
apolis.

Chairman's Address JOSEPH B. DE LEE, Chicago

The Conservative Treatment of Eclampsia (Lantern Demon-
stration) LYLE G. MCNEILE, Los Angeles

Pregnancy Changes in the Vaginal Epithelium in Relation to
the Vaginal Cycle (Lantern Demonstration)

M. EDWARD DAVIS, Chicago

Discussion to be opened by CARL G. HARTMAN, Baltimore

Friday, June 15—2 p. m.

Election of Officers

Electrocoagulation of Cervical Erosions and Endocervicitis in
the Late Puerperium (Lantern Demonstration)

RALPH L. BARRETT, New York

Discussion to be opened by HAROLD A. MILLER, Pitts-
burgh

Factors Predisposing to Carcinoma of the Uterus (Lantern
Demonstration) J. I. HOFBAUER, Cincinnati

Discussion to be opened by J. P. GREENHILL, Chicago

Comments on One Hundred Cases of Ectopic Pregnancy
Encountered in Private Practice (Lantern Demonstra-
tion) CHESTER M. ECHOLS, Milwaukee

Discussion to be opened by JOSEPH D. HEIMAN, Cin-
cinnati

Early Histologic Diagnosis of Carcinoma of the Uterine Cervix
(Lantern Demonstration) HENRY SCHMITZ, Chicago

Discussion to be opened by EMIL NOVAK, Baltimore

Demonstration of the Endometrium in Relief with Thorium
Dioxide Sol (Lantern Demonstration)

J. DUANE MILLER, Grand Rapids, Mich.

Discussion to be opened by HARVEY B. MATTHEWS,
Brooklyn

SECTION ON OPHTHALMOLOGY

MEETS IN LITTLE THEATER, ARENA FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

Chairman—WILLIAM C. FINNOFF, Denver

Vice Chairman—FRANK E. BURCH, St. Paul

Secretary—PARKER HEATH, Detroit

Executive Committee—HARRY FRIEDENWALD, Baltimore,
FREDERICK H. VERHOEFF, Boston, WILLIAM C. FINNOFF,
Denver

Wednesday, June 13—9 a. m.

Chairman's Address WILLIAM C. FINNOFF, Denver

The Ocular Lesions Resulting from Thallium Acetate Poison-
ing as Determined by Experimental Research (Lantern
Demonstration) CHARLES M. SWAB, Omaha

SYMPOSIUM ON TREATMENT OF RETINAL DETACH- MENT BY ELECTRICAL COAGULATION

Clinical Observations (Lantern Demonstration)

MARK J. SCHOENBERG, New York.

A New Technic and Case Reports (Lantern Demonstration)

CLIFFORD B. WALKER, Los Angeles

Blepharochalasis (Lantern Demonstration)

BENNETT Y. ALVIS, St. Louis

Diabetic Cataract (Lantern Demonstration)

C. S. O'BRIEN, Iowa City

Thursday, June 14—9 a. m.

Anterior Lenticonus (Lantern Demonstration)

BENJAMIN RONES, Baltimore

Transcranial Approach for Removal of Cavemous Hemangioma
of the Orbit (Lantern Demonstration)

A. W. ADSON and WILLIAM L. BENEDICT, Rochester,
Minn.

Observations of Four Thousand Optic Foramina in Human
Skulls of Known Origin (Lantern Demonstration)

JOHN E. L. KEYES, Youngstown, Ohio

Unilateral Central and Annular Scotoma Produced by Fracture
of the Optic Canal. Report of Two Cases (Lantern
Demonstration)

WALTER I. LILLIE, Philadelphia

Some Factors Concerned in the Correction of Aphakia

ALFRED COWAN, Philadelphia

Pulsating Exophthalmos Due to Internal Carotid Jugular
Aneurysm (Lantern Demonstration)

T. L. TERRY, Boston

Exhibition of Instruments and Appliances

Friday, June 15—9 a. m.

Election of Officers

Bacteriologic and Immunologic Considerations of Chronic
Uveitis ALBERT L. BROWN, Cincinnati

SYMPOSIUM ON STRABISMUS

Practical Details in the Orthoptic Treatment of Strabismus
(Lantern Demonstration) GEORGE P. GUIBOR, Chicago

Routine Muscle Examination Its Practical Application (Lan-
tern Demonstration)

JAMES WATSON WHITE, New York

Etiologic Diagnosis of Conjunctivitis (Lantern Demonstration)

PHILLIPS THYGESON, Iowa City

Occurrence of Malignant Conditions of the Eyeball Following
Trauma (Lantern Demonstration)

EDWARD STIEREN, Pittsburgh

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

MEETS IN LITTLE THEATER, ARENA FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

Chairman—WILLIAM P. WHERRY, Omaha

Vice Chairman—ROBERT F. RIDPATH, Philadelphia

Secretary—JOHN J. SHEA, Memphis, Tenn.

Executive Committee—GABRIEL TUCKER, Philadelphia, HAR-
RIS P. MOSHER, Boston, WILLIAM P. WHERRY, Omaha

Wednesday, June 13—2 p m

- Chairman's Address (Lantern Demonstration)
WILLIAM P WHERRY, Omaha
- The Tonsils, Their Function and Indications for Their Removal (Lantern Demonstration) L W DEAN, St Louis
- The Structure of the Secondary Nodule of the Tonsil (Lantern Demonstration) FRANK J NOVAK JR, Chicago
- The Use of Reconstructive Surgery in Certain Types of Deformities of the Face (Lantern Demonstration)
GORDON B NEW, Rochester, Minn
- The Importance of Allergy in the Etiology and Treatment of Nasal Mucous Polyps (Lantern Demonstration)
R A KERN and H P SCHENCK, Philadelphia
- An Attempt to Correlate the Various Theories of Vasomotor Disturbances of the Nasal and Bronchial Tracts
HAROLD G TOBEY Boston

Thursday, June 14—2 p m

- Agranulocytic Angina ROBERT F RIDPATH, Philadelphia
- X-Ray Changes in the Petrous Portion of the Temporal Bone Without Clinical Manifestations (Lantern Demonstration)
GEORGE M COATES MATTHEW S ERSNER and DAVID MYERS, Philadelphia
- Practical Points in the Radical Mastoid Operation (Lantern Demonstration) CLARENCE H SMITH New York
- Changes in the Lysozyme Content of the Nasal Secretion During Colds ANDERSON C HILDING, Duluth, Minn
- Experimental Studies in Vascular Repair A Report of Two Hundred Experimental Studies (Lantern and Motion Picture Demonstration)
O JASON DIXON, Kansas City, Mo
- Diagnostic Factors Concerning Herpes Zoster Oticus
RALPH A FENTON Portland, Ore

Friday, June 15—2 p m

- Election of Officers**
- Hearing Reclamation and Preservation in the Moderately Deafened Child Management and Treatment Based on Ten Years of Clinical and Laboratory Research (Lantern Demonstration) EDMUND P FOWLER, New York
- Prenatal Medication as a Possible Etiologic Factor of Deafness in the New-Born
H MARSHALL TAYLOR, Jacksonville, Fla
- Conservative Surgical Treatment of Hypertrophic Rhinitis (Lantern Demonstration)
HOWARD V DUTROW, Dayton, Ohio
- The Association of Middle Ear Infection with Sinus Disease (Lantern Demonstration)
M M CULLOM, Nashville, Tenn
- An X-Ray Study of the Maxillary Antrum Before and After Operation (Lantern Demonstration)
EDWARD KING Cincinnati
- New Adaptation of X-Ray Prints and Slides Giving Stereoscopic Effect
WALTER H THEOBALD, Chicago

SECTION ON PEDIATRICS

MEETS IN BALLROOM, FOURTH FLOOR CLEVELAND
PUBLIC AUDITORIUM

OFFICERS OF SECTION

- Chairman—ALFRED A WALKER, Birmingham, Ala
- Vice Chairman—C W BURHANS, Lakewood, Ohio
- Secretary—RALPH M TYSON Philadelphia
- Executive Committee—JAY I DURAND Seattle FREDERIC W SCHLUTZ, Chicago, ALFRED A WALKER Birmingham, Ala

Wednesday, June 13—9 a m

- Further Studies on Tungsten Filament Radiation (Dual Purpose Lighting) (Lantern and Motion Picture Demonstration)
HENRY J GERSTENBERGER A J HORESH J D NOURSE and A L VAN HORN Cleveland
- Discussion to be opened by A GRAEME MITCHELL Cincinnati and HUGH J LESLIE Cleveland

- The Value of the Calmette Vaccination in Prevention of Tuberculosis in Childhood (Lantern Demonstration)
ARVID WALLGREN, Goteborg, Sweden
- The Effect of Initial Tuberculous Infection on Subsequent Tuberculous Lesions (Lantern Demonstration)
J A MYERS, Minneapolis
- Discussion to be opened by HORTON R CASPARIS, Nashville, Tenn, and W AMBROSE MCGEE, Richmond, Va
- The Application of Determinations of Fetal Size in Utero to the Problem of Reducing the Premature Infant Mortality (Lantern Demonstration)
STEWART H CLIFFORD Boston
- Discussion to be opened by FRED L ADAIR and JULIUS H HESS, Chicago
- A Study of the Influence of Breast and Artificial Feeding on the Morbidity and Mortality of Twenty Thousand Infants (Lantern Demonstration)
CLIFFORD G GRULEE and HEYWORTH N SANFORD, Chicago, and PAUL H HERRON, Spokane, Wash
- Discussion to be opened by LAURENCE R DEBUYS, New Orleans
- The Pathology of Pneumonia in Infancy (Lantern Demonstration)
CHARLES HENDEE SMITH, IRVING GRAEF and ELIZABETH H T ANDREWS, New York
- Discussion to be opened by FRANK W KONZELMANN, Philadelphia, and KARL E KASSOWITZ, Milwaukee

Thursday, June 14—9 a m

- Chronic Atopic Eczema (Neurodermatitis) in Childhood
LEWIS W HILL, Boston
- Discussion to be opened by MARION B SULZBERGER, New York and J VICTOR GREENEBAUM, Cincinnati
- Chairman's Address One Dose Alum Toxoid in Diphtheria Immunization
ALFRED A WALKER, Birmingham, Ala
- Factors That Influence Rheumatic Disease in Childhood (Lantern Demonstration)
ALBERT D KAISER Rochester, N Y
- Discussion to be opened by HUGH McCULLOCH, St Louis, and ALBERT J BEIL, Cincinnati
- Therapeutic Results with the Pituitary Growth Hormone (Lantern Demonstration)
ROBERT L SCHAEFER, Detroit
- Discussion to be opened by ROY G HOSKINS, Boston
- The Problem of Accidental Poisoning in Childhood (Lantern Demonstration) JOHN AIKMAN, Rochester, N Y
- Discussion to be opened by S W CLAUSEN, Rochester, N Y, and C W WICKOFF, Cleveland
- Diagnosis and Treatment of Lung Abscess in Children (Lantern Demonstration) DAVID T SMITH, Durham N C
- Discussion to be opened by LOUIS H CLERF, Philadelphia, and J W EPSTEIN, Cleveland

Friday, June 15—9 a m

- Election of Officers**
- Theory and Practice of Parenteral Fluid Administration (Lantern Demonstration) ALEXIS F HARTMAN, St Louis
- Discussion to be opened by F W SCHLUTZ, Chicago, and ARTHUR G HELMICK, Columbus Ohio
- A Study of Vaccination in Five Hundred New-Born Infants (Lantern Demonstration)
H H DONNALLY, Washington D C
- Discussion to be opened by J A DOULL, Cleveland
- The Immunization of School Children Against Whooping Cough (Lantern Demonstration)
J M FRAWLEY, Fresno, Calif
- Discussion to be opened by LOUIS W SAUTER Evanston, Ill, and H F HELMHOLZ, Rochester, Minn
- Antitoxin is No Antitoxin in Scarlet Fever (Lantern Demonstration)
JAMES E BOWMAN and P F LUCCHESI, Philadelphia
- Discussion to be opened by JOHN A TOOMEY, Cleveland
- The Secondary Case of Scarlet Fever (Lantern Demonstration)
ARCHIBALD L HOYNE and JOHN HAYS BAILEY, Chicago
- Discussion to be opened by JOHN A TOOMEY Cleveland and D L RICHARDSON Providence, R I

**SECTION ON PHARMACOLOGY
AND THERAPEUTICS**MEETS IN SOUTH HALL C, FOURTH FLOOR,
CLEVELAND PUBLIC AUDITORIUM**OFFICERS OF SECTION**

Chairman—JOHN H. MUSSER, New Orleans

Vice Chairman—C. H. GREENE, New York

Secretary—RUSSELL L. HADEN, Cleveland

Executive Committee—R. L. LEVY, New York, E. M. K. GEILING, Baltimore, JOHN H. MUSSER, New Orleans

Wednesday, June 13—9 a m

Clinical Experiences with Thetevin, a Cardiac Glucoside (Lantern Demonstration)

HARRY L. ARNOLD, Honolulu, T. H., WILLIAM S. MIDDLETON, Madison, Wis., and K. K. CHEN, Indianapolis

Discussion to be opened by R. WESLEY SCOTT, Cleveland

Effects of Tissue Extracts on Muscle Pain of Ischemic Origin (Lantern Demonstration)

NELSON W. BARKER and GRACE M. ROTH, Rochester, Minn.

Discussion to be opened by E. V. ALLEN, Rochester, Minn., and WALLACE S. DUNCAN, Cleveland

Oxygen in the Treatment of Acute Coronary Occlusion

ALVAN L. BARACH and ROBERT L. LEVY, New York
Discussion to be opened by WALTER M. BOOTHBY, Rochester, Minn., and A. CARLTON ERNSTENE, Cleveland

Studies on the Thyrotropic Hormone of the Anterior Pituitary (Lantern Demonstration)

JAMES B. COLLIP and E. M. ANDERSON, Montreal, Canada

Action of Iodine in Thyrotoxicosis with Special Reference to Refractoriness (Lantern Demonstration)

JAMES H. MEANS and JACOB LERMAN, Boston

Pharmacology of the Thyroid in Man (Lantern Demonstration)

W. O. THOMPSON, Chicago

Discussion on papers of DRS. COLLIP and ANDERSON, MEANS and LERMAN and DR. THOMPSON to be opened by GEORGE W. CRILE, Cleveland, ANTON J. CARLSON, Chicago, HERRMANN L. BLUMGART, Boston, A. C. IVY, Chicago, GEORGE M. CURTIS, Columbus, Ohio, and E. C. KENDALL, Rochester, Minn.

Thursday, June 14—9 a m

The Differential Diagnosis and Therapeutic Rationale of Leukopenic States (Lantern Demonstration)

CHARLES A. DOAN, Columbus, Ohio

Discussion to be opened by ROY R. KRACKE, Emory University, Ga., and E. B. KRUMBHAR, Philadelphia

Hemoglobin and Plasma Protein Regeneration as Influenced by Amino Acids and Proteins in Diet (Lantern Demonstration)

GEORGE H. WHIPPLE, Rochester, N. Y.

The Diagnosis and Treatment of the Iron Deficiency Anemias (Lantern Demonstration)

FRANK H. BETHELL, Ann Arbor, Mich.

An Assay of Various Extracts of Liver for Intramuscular Use (Lantern Demonstration)

WILLIAM DAMESHEK and WILLIAM B. CASTLE, Boston

Discussion on papers of DRS. WHIPPLE, BETHELL, and DAMESHEK and CASTLE to be opened by RAPHAEL ISAACS, Ann Arbor, Mich., L. G. ZERFAS, Indianapolis, GEORGE R. MINOT, Boston, and CYRUS C. STURGIS, Ann Arbor, Mich.

Chairman's Address JOHN H. MUSSER, New Orleans

Treatment of the Common Cold (Lantern Demonstration)

H. S. DIEHL, Minneapolis
Discussion to be opened by GERALD S. SHIBLEY, Cleveland, K. K. CHEN, Indianapolis, and H. H. FELLOWS, New York**Friday, June 15—9 a m****Election of Officers**

A Study of the Effect of Caffeine on Rabbits (Lantern Demonstration)

C. GLENVILLE GIDDINGS JR. and E. L. BISHOP, Atlanta, Ga.

Discussion to be opened by E. W. EDMUNDS, Ann Arbor, Mich.

The Relief of Menopause Symptoms by Follicular Hormone Therapy (Lantern Demonstration)

E. L. SEVRINGHAUS, Madison, Wis.

Discussion to be opened by EMIL NOVAK, Baltimore, J. P. PRATT, Detroit, and E. P. McCULLAGH, Cleveland

Studies of Morphine Substitutes (Lantern Demonstration)

E. W. EDMUNDS and NATHAN B. EDDY, Ann Arbor, Mich.

The Use of Dihydromorphinon Hydrochloride in the Pain of Cancer (Lantern Demonstration)

The Influence of the Cortex on Gastro-Intestinal Movements
(Lantern Demonstration)
JAMES W WATTS, Philadelphia
Discussion on papers of DRS KENNARD and WATTS to
be opened by JOHN PAUL QUIGLEY, Cleveland, and
PAUL C BUCY, Chicago

OCCIPITAL LOBES

- Structure of the Retina and Its Cerebral Representation in
Primates and in Man (Lantern Demonstration)
STEPHEN POLJAK, Chicago
A Phylogenic Interpretation of the Functions of the Visual
Cortex (Lantern Demonstration)
DONALD MARQUIS New Haven, Conn
Discussion on papers of DRS POLJAK and MARQUIS to
be opened by FRANKLIN JELSMAN, Louisville, Ky, and
THOMAS J HELDT, Detroit

Friday, June 15—9 a m

Election of Officers

- Multiple Sclerosis Cervicodorsal Sympathectomy as a Relief
Measure (Lantern Demonstration)
FREDERICK S WETHERELL, Syracuse, N Y
Discussion to be opened by NOBLE R CHAMBERS,
Syracuse, N Y
Spinal Drainage of Repeated Lumbar Punctures in Traumatic
Lesions of the Central Nervous System
WILLIAM SHARPE, New York
Discussion to be opened by FOSTER KENNEDY, New
York, and TEMPLE S FAX, Philadelphia
Muscular Dystrophy, Muscular Atrophy and Myasthenia
Gravis Review of Clinical and Biochemical Studies of
the Effects of Amino Acid (Lantern Demonstration)
CARLO J TRIPOLI WILLIAM M MCCORD, JEROME E
ANDES and HOWARD H BEARD, New Orleans
Discussion to be opened by WALTER M BOOTHBY,
Rochester Minn, and HANS H REESE, Madison, Wis
Physiologic and Psychologic Phenomena Produced by a Pro-
longed Vigil (Lantern Demonstration)
SIEGFRIED E KATZ and CARNEY LANDIS, New York
Discussion to be opened by CLARENCE O CHENEY, New
York, and LLOYD H ZIEGLER, Albany, N Y
The Treatment of Psychoneuroses in General Practice
LAUREN H SMITH, Philadelphia
Discussion to be opened by JOSEPH YASKIN, Philadelphia,
and ALAN D FINLAYSON, Cleveland
Modern State Hospital Treatment of Mental Diseases

SYPHILOLOGY**

MEETS IN CLUB ROOM B, THIRD FLOOR, CLEVELAND
PUBLIC AUDITORIUM

OFFICERS OF SECTION

- Chairman—C GUY LANE, Boston
Vice Chairman—CHARLES C TOMLINSON, Omaha
Secretary—HARRI R FOERSTER, Milwaukee
Executive Committee—GEORGE M MACKEE, New York
FRANCIS EUGENE SENEAR, Chicago, C GUY LANE, Boston

Wednesday, June 13—9 a m

- Chairman's Address (Lantern Demonstration)
C GUY LANE, Boston
Necrobiosis Lipoidica Diabeticorum (Lantern Demonstration)
ERWIN P ZEISLER and MARCUS R CARO, Chicago
Clinical Mutations in Lymphoblastomas (Lantern Demonstra-
tion) FRANK STILES JR, Ann Arbor, Mich
Is Spiegler-Fendt Sarcoid a Clinical or Histologic Entity?
GEORGE M LEWIS New York
Studies on the Specificity of a Streptococcus Isolated from
Cases of Pemphigus Preliminary Report (Lantern
Demonstration) ASHTON L WELSH, Rochester, Minn

- Streptococcic Infections Simulating Ringworm of the Hands and Feet (Lantern Demonstration)
JAMES HERBERT MITCHELL, Chicago
- The Roentgen Unit in Dermatology (Lantern Demonstration)
GEORGE M. MACKEE and ANTHONY C. CIPOLLARO, New York
- The Role of High Frequency Currents in the Performance and Histologic Interpretation of Biopsy Samples (Lantern Demonstration)
FRED D. WEIDMAN and JACQUES P. GUEQUIERRE, Philadelphia

Thursday, June 14—9 a m

- Urinary Proteose in Eczema (Lantern Demonstration)
THEODORE CORNBIET and M. A. KAPLAN, Chicago
- The Present Status of the Specific Diagnosis and Treatment of the Allergic Diseases of the Skin
ARTHUR F. COCA, New York
- Ragweed Dermatitis (Lantern Demonstration)
LOUIS A. BRUNSTING and C. R. ANDERSON, Rochester, Minn.
- Some Observations on Light Sensitive Dermatoses (Lantern Demonstration)
NELSON PAUL ANDERSON and SAMUEL AYRES JR., Los Angeles
- Acneiform Eruptions of the Face Etiologic Importance of Specific Foods (Lantern Demonstration)
CLEVELAND J. WHITE, Chicago
- Early Cutaneous Carcinoma (Lantern Demonstration)
RICHARD L. SUTTON JR., Kansas City, Mo.
- Dioxanthranol 1-8 as a Substitute for Chrysarobin
HERMAN BEERMAN, GEORGE V. KUCHAR, DONALD M. PILLSBURY and JOHN H. STOKES, Philadelphia
- Verruca Peruana as Observed in Peru (Lantern Demonstration)
HOWARD FOX, New York

Friday, June 15—9 a m

- Election of Officers
- The Treatment of Hemorrhagic Symptoms with Snake Venom (Lantern Demonstration)
SAMUEL M. PECK, New York
- The Frei Test for Lymphogranuloma Inguinale Recovery of the Antigen from a Pustular Reaction (Lantern Demonstration)
MAURICE J. STRAUSS and MARION E. HOWARD, New Haven, Conn.
- Organic Luetin Its Value in Diagnosis and Treatment of Syphilis A Study of Five Hundred Cases
LESLIE P. BARKER, New York
- The Treatment of Syphilis with Hyperpyrexia (Lantern Demonstration)
NORMAN N. EPSTEIN and MAURICE COHEN, San Francisco
- Sulpharsphenamine Bismuth (Bismarsen) in the Treatment of Congenital Syphilis A Five Years Appraisal (Lantern Demonstration)
STANLEY O. CHAMBERS and GEORGE F. KOETTER, Los Angeles
- Arsphenamine Sensitization Dermatitis An Attempt at Sensitizing Patients by Intradermal Neoarsphenamine (Lantern Demonstration)
ARTHUR G. SCHOCH, Dallas, Texas
- The Application of the Intravenous Drip Method of Chemotherapy as Illustrated by Massive Doses of Neoarsphenamine in the Treatment of Early Syphilis (Lantern Demonstration)
LOUIS CHARGIN, New York

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

MEETS IN SOUTH HALL B THIRD FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

- Chairman—WILSON G. SMILLIE, Boston
- Vice Chairman—JOHN P. KOEHLER, Milwaukee
- Secretary—R. R. SAYERS, Washington, D. C.
- Executive Committee—J. E. GORDON, Detroit, J. N. BAKER, Montgomery, Ala., WILSON G. SMILLIE, Boston

Wednesday, June 13—2 p m

SYMPOSIUM ON LEAD POISONING

- Chairman's Address (Lantern Demonstration)
WILSON G. SMILLIE, Boston.
- Epidemiology of Lead Poisoning
A. J. LANZA, New York.
- Chemistry of Lead in the Body (Lantern Demonstration)
JOSEPH C. AUB, Boston
- Normal Absorption and Excretion of Lead (Lantern Demonstration)
ROBERT A. KEHOE, Cincinnati
- Symptoms in Early Stages of Lead Poisoning
R. R. JONES, Washington, D. C.
- Control of Lead Poisoning in the Worker (Lantern Demonstration)
EUSTON L. BELKNAP, Milwaukee
- Recent Progress in the Treatment of Plumbism (Lantern Demonstration)
IRVING GRAY, Brooklyn

Thursday, June 14—2 p m

PUBLIC HEALTH

- The Relation of Postgraduate Medical Instruction to Public Health
LEROY E. PARKINS, Boston
- The Response of Peritoneal Tissue to Dusts Introduced as Foreign Bodies (Lantern Demonstration)
JOHN W. MILLER and R. R. SAYERS, Washington, D. C., and WILLIAM P. YANT, Pittsburgh
- The Estimation of Functional Disability in the Pulmonary Fibroses (Lantern Demonstration)
A. HURTADO, W. W. PRAY, N. KALTREIDER and WILLIAM S. MCCANN, Rochester, N. Y.
- The Control of Occupational Diseases by Laboratory Methods
C. O. SAPPINGTON, Chicago
- Carbon Tetrachloride as an Industrial Hazard
P. A. DAVIS, Akron, Ohio
- The Effects of Consolidation of State Health Welfare and Licensure Functions to Preventive Medicine (Lantern Demonstration)
F. D. STRICKER, Portland, Ore.
- Some Phase of Current Medical Relief Problems (Lantern Demonstration)
H. JACKSON DAVIS, Albany, N. Y.

Friday, June 15—2 p m

Election of Officers

EPIDEMIC ENCEPHALITIS

- The Encephalitis Problem (Lantern Demonstration)
JOSEPHINE B. NEAL, New York
- 1933 OUTBREAK
- Epidemiology
J. P. LEAKE, Washington, D. C.
- Pathology (Lantern Demonstration)
HOWARD ANDERSON MCCORDOCK, St. Louis
- Etiology (Lantern Demonstration)
RALPH S. MUCKENFUSS, St. Louis
- Diagnosis (Lantern Demonstration)
THEODORE C. HENPELMANN, St. Louis
- Treatment
J. W. ESCHENBRENNER, St. Louis
- Prognosis
ANDREW B. JONES, St. Louis
- Handling the Epidemic
JOSEPH F. BREDECK and PAUL J. ZENTAY, St. Louis

SECTION ON UROLOGY

MEETS IN CLUB ROOM B THIRD FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

- Chairman—HARRY CULVER, Chicago
- Vice Chairman—W. M. KEARNS, Milwaukee
- Secretary—J. H. MORRISSEY, New York
- Executive Committee—J. D. BARNEY, Boston, N. G. ALCOCK, Iowa City, HARRY CULVER, Chicago

Wednesday, June 13—2 p m

SYMPOSIUM ON GONORRHEA

- Immunologic Problems in Gonorrhea
PERCY S. PELOUZE, Philadelphia
- The Treatment of Gonorrhea Based on Laboratory Observations During the Course of the Disease
RUSSELL B. HERROLD, Chicago
- Methods of Treatment of Gonorrhea in Women (Lantern Demonstration)
EMILY D. BARRINGER, New York
- Discussion on papers of Drs. PELOUZE, HERROLD and BARRINGER to be opened by AUGUSTUS L. HARRIS, Brooklyn, HENRY W. E. WALTHER, New Orleans, HERBERT T. HAYES, Houston, Texas and ROY W. MOHLER, Philadelphia

Results with Corbus Ferry Bouillon Filtrate and Other Forms of Intradermal Therapy in the Treatment of Gonorrhea (Lantern Demonstration)

R E CUMMING and ROBERT A BURHANS, Detroit
Discussion to be opened by BUDD C CORBUS, Chicago

The Criteria of Cure of Gonorrhea

AMBRSE J KING, London, England
Discussion to be opened by C T STEPITA, New York

Instrumental Methods of Procedure in the Treatment of the Prostatic and Vesicular Infections (Lantern Demonstration)

JOSEPH F MCCARTHY, New York

The Treatment of Chronic Prostatitis by Incision with Electrocautery (Lantern Demonstration)

GERSHOM J THOMPSON, Rochester Minn
Discussion on papers of DRS MCCARTHY and THOMPSON to be opened by W N TAYLOR, Columbus, Ohio, and E O SMITH Cincinnati

Indications and Methods in Handling the Surgical Complications Occurring in the Treatment of Gonorrhea

ALBERT E GOLDSTEIN, Baltimore

Discussion to be opened by MILEY B WESSON, San Francisco and ELMER HESS, Erie, Pa

Presentation of a New Dilating Urethroscope for Women (Lantern Demonstration)

RALPH L DOURMASHKIN New York

Thursday, June 14—2 p m

Chairman's Address The Importance of the Streptococcus in Genito-Urinary Disease

HARRY CULVER, Chicago

A Simplified Treatment of Bacilluria

ANSON L CLARK and B F KELTZ, Oklahoma City

The Necessity for the Standardization of the Treatment of Bacilluria (Lantern Demonstration)

ALBERT M CRANCE, Geneva, N Y

Discussion on papers of DRS CULVER, CLARK and KELTZ, and CRANCE to be opened by WILLIAM P HERBST Jr Washington, D C, and IRA R SISK, Madison, Wis

SYMPOSIUM ON GENITO URINARY TUBERCULOSIS

The Incidence of Renal Tuberculosis in Five Hundred Autopsies for General and Pulmonary Tuberculosis (Lantern Demonstration)

MONROE E GREENBERGER and LEONARD P WERSHUB New York and OSCAR AUERBACH West New Brighton, S I, N Y

Discussion to be opened by ROY B HENLINE New York and THOMAS D MOORE, Memphis, Tenn

Tuberculous Nephritis (Lantern Demonstration)

FREDERICK LIEBERTHAL, Chicago

Discussion to be opened by WILLIAM ROSENBERG, Cleveland, and BORIS E GREENBERG, Boston

Does the Diagnosis of Unilateral Renal Tuberculosis Always Indicate Nephrectomy?

STANLEY R WOODRUFF, Jersey City N J and H C BUMPUS JR Pasadena, Calif

Discussion to be opened by N G ALCOCK, Iowa City, J C PENNINGTON, Nashville, Tenn, and R M LECOMTE, Washington, D C

Genital Tuberculosis (Lantern Demonstration)

HUGH H YOUNG Baltimore

Discussion to be opened by WILLIAM E LOWER Cleveland and W F BRAASCH, Rochester Minn

Treatment of Urinary Tuberculosis—Old and New

EDWARD L KEYES, New York

Discussion to be opened by W G SHULTZ Tucson, Ariz, CHARLES M MCKENNA, Chicago, and C J McDEVITT Cincinnati

Quartz Light Therapy in the Treatment of Bladder Tuberculosis (Lantern Demonstration)

STANLEY L WANG New York

Friday, June 15—2 p m

Election of Officers

SYMPOSIUM ON UROLITHIASIS

The Present Conception of Renal Lithiasis (Lantern Demonstration)

VIRGIL S COUNSELLER Rochester, Minn and J B PRIESTLY, Des Moines Iowa

Discussion to be opened by L LICHTWITZ and JEROME M LATCH New York

Experimental Production and Dissolution of Urinary Calculi with Clinical Application (Lantern Demonstration)

CHARLES C HIGGINS, Cleveland

Discussion to be opened by WILLIAM J ENGEL, Cleveland, and GEORGE H EWELL, Madison, Wis

Bilateral Urinary Calculi The Medical and Surgical Handling of the Various Problems Involved (Lantern Demonstration)

ALEXANDER R STEVENS, New York

Discussion to be opened by J S LEWIS JR, Youngstown, Ohio, and MOSES SWICK, New York

Recurrent Urinary Calculi Consideration of Etiologic Factors and Clinical Management (Lantern Demonstration)

LINWOOD D KEISER Roanoke, Va

Discussion to be opened by THOMAS P SHUPE, Cleveland, RICHARD CHUTE, Boston, and FRANCIS P TWINEM, New York

The Medical and Surgical Treatment of Calculous Anuria (Lantern Demonstration)

GEORGE F CAHILL, New York

Discussion to be opened by HARRY R TRATTNER, Cleveland, and GORDON F MCKIM, Cincinnati

The Indications for Operation and Treatment of Impacted Ureteral Calculus (Lantern Demonstration)

FREDERIC E B FOLEY, St Paul

Discussion to be opened by OSWALD S LOWSLEY, New York, and ARTHUR R KNAUF, Tampa, Fla

Present-Day Management of Bladder Stones with a Description of Visualized Litholapaxy (Lantern Demonstration)

ABRAHAM RAVICH, Brooklyn

SECTION ON ORTHOPEDIC SURGERY

MEETS IN SOUTH HALL A, SECOND FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

Chairman—JAMES S SPEED, Memphis, Tenn

Vice Chairman—R D SCHROCK, Omaha

Secretary—FREMONT A CHANDLER, Chicago

Executive Committee—JAMES WARREN SEVER Boston, W BARNETT OWEN, Louisville, Ky, JAMES S SPEED, Memphis, Tenn

Wednesday, June 13—2 p m

The Treatment of Committted Fracture of the Patella in Which There Are One Large Fragment and Several Small Fragments (Lantern Demonstration)

J E M THOMSON, Lincoln, Neb

Discussion to be opened by JAMES S SPEED, Memphis, Tenn, H R CONN, Akron, Ohio, and MARCUS H HOBART, Evanston, Ill

Report of One Hundred Cases of Fracture of the Hip (Lantern Demonstration)

LOUIS G HOWARD, Boston

Discussion to be opened by DALLAS B PHEMISTER Chicago ARCHIBALD F O DONOGHUE, Sioux City, Iowa, E T EVANS, Minneapolis and J LAURENCE JONES, Kansas City, Mo

End Result Study of Tuberculosis of the Hip Joint Treated by Fusion A Study of One Hundred and Seventy Cases (Lantern Demonstration)

HALFORD HALLOCK and JAMES W TOUMER JR, New York

Discussion to be opened by HEARY W MEYERDING, Rochester, Minn, FRANK R OBER Boston C H HEYMAN, Cleveland, and JOSEPH S BARR, Boston

The Treatment of Simple Foot Imbalance (Lantern and Motion Picture Demonstration)

REX L DIVELEY Kansas City, Mo

Discussion to be opened by CARL E BADGLEY Ann Arbor, Mich, THEODORE A WILLIS, Cleveland LEWIS CLARK WAGNER and JOHN JOSEPH NUTT, New York, and J J KURLANDER, Cleveland

Nonoperative Treatment of Fractures of the Bones of the Forearm, with Special Reference to the Treatment of These Fractures in Children and Adolescents A Report of One Hundred and Fifty Consecutive Recent Cases (Lantern Demonstration)

VOIGT MOONEY, Pittsburgh
Discussion to be opened by RUDOLPH S REICH and WALLACE S DUNCAN Cleveland and D H LEVINTHAL Chicago

The Growth Disk

ARTHUR G DAVIS, Erie, Pa

Thursday, June 14—2 p m

Congenital Pseudarthrosis of the Tibia (Lantern Demonstration) PAUL CRENSHAW COLONNA, New York
Discussion to be opened by ARMITAGE WHITMAN, New York, PHILIP LEWIN, Chicago, BURT G. CHOLLET, Toledo, Ohio, and HENRY W. MEYERDING, Rochester, Minn

Nonunion in Fractures of the Shaft of Humerus A Report on Four Cases (Lantern and Motion Picture Demonstration) JAMES WARREN SEVER, Boston
Discussion to be opened by DALLAS B. PHEMISTER, Chicago, WILLIAM B. OWEN, Louisville, Ky., and WILLIAM L. SNEED, New York

Chairman's Address An Analysis of End Results in the Treatment of Central Fractures of the Neck of the Femur (Lantern Demonstration)

JAMES S. SPEED, Memphis, Tenn

Disabilities of the Hand Resulting from Loss of Joint Function (Lantern Demonstration) SUMNER L. S. KOCH, Chicago
Discussion to be opened by WALTER G. STERN, Cleveland, ARTHUR STEINDLER, Iowa City, and L. E. PAPURT, Cleveland

Statistical Analysis and Report on the Treatment of Five Hundred Cases of Congenital Dislocation of the Hip Bloodless and Open Reduction and Late Palliative Operations (Lantern Demonstration)

ARTHUR STEINDLER, ERNEST FREUND and JACOB KULOWSKI, Iowa City

Discussion to be opened by EDWIN W. RYERSON, Chicago, JOSEPH A. FRIBERG, Cincinnati, and SAMUEL L. ROBBINS, Cleveland

Dislocations of the Cervical Spine Some Predisposing Causes (Lantern Demonstration)

THEODORF P. BROOKES, St. Louis

Discussion to be opened by ROBERT D. SCHROCK, Omaha, and CARL B. DAVIS, Chicago

Injuries to the Vertebrae and Intervertebral Disks Following Lumbar Puncture (Lantern Demonstration)

CHARLES N. PLASE, Chicago

Discussion to be opened by R. WALLACE BILLINGTON, Nashville, Tenn. EDWARD L. COMPERE, Chicago, and C. G. BARBER, Cleveland

Friday, June 15—2 p m

Election of Officers

Treatment of Permanent Paralysis of Deltoid Muscle with Luxation at the Shoulder Joint (Lantern and Motion Picture Demonstration)

Discussion to be opened by SYLVAN L. HAAS, San Francisco, FRANK R. OBER, Boston, ROBERT D. SCHROCK, Omaha, and WALTER A. HOYT, Akron, Ohio

The Mechanics of the Function of the Viscera in the Upper Part of the Abdomen (Lantern Demonstration)

JOEL E. GOLDTHWAIT, Boston

Discussion to be opened by EDWIN W. RYERSON and EMIL D. HAUSER, Chicago

Coxa Magna A Condition of the Hip Related to Coxa Plana (Lantern Demonstration)

ALBERT B. FERGUSON and M. BECKETT HOWORTH, New York

Discussion to be opened by ARTHUR T. LEGG, Boston, and OSCAR L. MILLER, Charlotte, N. C.

The Changes in Autogenous Bone Transplants (Lantern Demonstration) C. HOWARD HATCHER, Chicago

Discussion to be opened by PAUL B. MAGNUSON, Chicago, and ESLE ASBURY, Cincinnati

Fracture of Both Bones of the Leg Treatment by a Modified Boehler Method with a New Apparatus (Lantern Demonstration)

R. A. GRISWOLD, Louisville, Ky.

Discussion to be opened by WILLIAM B. OWEN, Louisville, Ky., J. A. CALDWELL, Cincinnati, and MAXWELL HARBIN, Cleveland

The Influence of the Shoe on Gait as Recorded by Electrobasograms and Slow Motion Pictures (Lantern and Motion Picture Demonstration)

R. PLATO SCHWARTZ, Rochester, N. Y.

Discussion to be opened by FRANK R. OBER, Boston, ARTHUR STEINDLER, Iowa City, and G. I. BAUMAN, Cleveland

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN SOUTH HALL B, THIRD FLOOR,
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

Chairman—ALBERT F. R. ANDRESEN, Brooklyn

Vice Chairman—WALTER A. FANSLER, Minneapolis

Secretary—H. L. BOCKAUS, Philadelphia

Executive Committee—GEORGE B. EUSTERMAN, Rochester, Minn., CURTICE ROSSER, Dallas, Texas, ALBERT F. R. ANDRESEN, Brooklyn

Wednesday, June 13—9 a m.

The Morphology and Function of a Continuous Reticular Coat of the Small Intestine (Lantern Demonstration)

LEWIS GREGORY COLE, New York

Discussion to be opened by EUGENE P. PENDERGRASS, Philadelphia

Regional (Terminal) Ileitis Its Roentgen Diagnosis (Lantern Demonstration)

JOHN L. KANTOR, New York

Discussion to be opened by HARRY M. WEBER, Rochester, Minn., and JAMES T. CASE, Chicago

Intestinal Tuberculosis An Analysis of One Thousand Autopsies, with Remarks on the Early Diagnosis by Double Contrast Barium Enema (Lantern Demonstration)

RUSSELL S. BOLES and JACOB GERSHON-COHEN, Philadelphia

Discussion to be opened by EDGAR MAYER, New York, and BENJAMIN H. ORNDORFF, Chicago

Peptic Esophagitis A New Clinical Entity (Lantern Demonstration)

ASHER WINKELSTEIN, New York

Discussion to be opened by CHEVALIER JACKSON, Philadelphia, and RUDOLPH KRAMER, New York

Gastroscopy (Lantern and Motion Picture Demonstration)

CHEVALIER JACKSON and CHEVALIER L. JACKSON, Philadelphia

Discussion to be opened by GABRIEL TUCKER and WILLIAM A. SWALM, Philadelphia

Histopathology of the Anal Crypts (Lantern Demonstration)

CLAUDE C. TUCKER and C. ALEXANDER HELLWIG, Wichita, Kan.

Discussion to be opened by CHARLES E. POPE, Evanston, Ill., and LOUIS J. HIRSCHMAN, Detroit

Thursday, June 14—9 a m.

Chairman's Address The Undergraduate Teaching of Gastroenterology in American Medical Schools (Lantern Demonstration)

ALBERT F. R. ANDRESEN, Brooklyn

Digestive Manifestations of Gout and Their Treatment (Lantern Demonstration)

ANTHONY BASSLER, New York

Discussion to be opened by HORACE W. SOPER, St. Louis, and E. W. SHANK, Dayton, Ohio

Gastro-Intestinal Manifestations of Urologic Disease (Lantern Demonstration)

SIDNEY A. PORTIS and J. S. GROVE, Chicago

Discussion to be opened by HARLOW BROOKS, New York, and CHARLES M. MCKENNA, Chicago

Jaundice A Review of Experimental Investigations (Lantern Demonstration)

F. C. MAYN and J. L. BOLLMAN, Rochester, Minn.

Discussion to be opened by I. S. RAVDIN, Philadelphia, and A. C. IVY, Chicago

The Galactose and Urobilinogen Tests in the Differential Diagnosis of Obstructive and Intrahepatic Jaundice (Lantern Demonstration)

DAVID H. ROSENBERG, Chicago

Discussion to be opened by M. A. BLANKENHORN, Cleveland, and LEON SCHIFF, Cincinnati

Latent and Slight Jaundice The Significance of Slightly Elevated Concentrations of Serum Bilirubin

H. M. ROZENDAAL, M. W. COMFORT and A. M. SNELL, Rochester, Minn.

Discussion to be opened by A. H. AARON, Buffalo, and V. C. ROWLAND, Cleveland

Gonococcal Infection of the Rectum

CLEMENT L. MARTIN, Chicago

Discussion to be opened by HERBERT T. HAYES, Houston, Texas, and CURTICE ROSSER, Dallas, Texas

Friday, June 15—9 a m

Election of Officers

- Cancer of the Rectum JOSEPH W RICKETTS Indianapolis
Discussion to be opened by FRED W RANKIN Lexington, Kj, and DUDLEY A SMITH San Francisco
- Krukenberg Tumor (Lantern Demonstration)
F G RUNYON Reading Pa
Discussion to be opened by JOSEPH C BLOODGOOD Baltimore and HARRY E BACON Philadelphia
- Proteins Versus Carbohydrates A Study of Their Gastric Digestion MARTIN E REHFUSS Philadelphia
Discussion to be opened by J EARL THOMAS Philadelphia, and ERNEST H GAITHER Baltimore
- The Unstable or Irritable Duodenum Clinical Observations in One Hundred Cases
JULIUS FRIEDENWALD and MAURICE FELDMAN, Baltimore
Discussion to be opened by ELMER L EGGLESTON Battle Creek Mich, and JOHN G MATEER Detroit
- Pain in Benign Ulcers of the Esophagus Stomach and Small Bowel The Diagnostic Significance of Type and Radiation with Some Observations of Pain Conduction Pathways (Lantern Demonstration)
ANDREW B RIVERS Rochester Minn
Discussion to be opened by RALPH C BROWN and FRANK SMITHIES Chicago
- Complications of Peptic Ulcer Their Prognostic Significance (Lantern Demonstration)
SARA M JORDAN and EVERETT D KIEFER Boston
Discussion to be opened by BURRILL B CROHN New York, and J TATE MASON, Seattle

SECTION ON RADIOLOGY

MEETS IN NORTH HALL, LOWER LEVEL
CLEVELAND PUBLIC AUDITORIUM

OFFICERS OF SECTION

- Chairman—A U DESJARDINS Rochester Minn
Vice Chairman—AMEDEE GRANGER New Orleans
Secretary—JOHN T MURPHY Toledo Ohio
Executive Committee—HENRY K PANCOAST Philadelphia
GEORGE W GRIER Pittsburgh A U DESJARDINS Rochester, Minn

Wednesday, June 13—9 a m

- Chairman's Address A U DESJARDINS Rochester Minn
- The Role of X-Ray Wavelength in Skin Tolerance (Lantern Demonstration)
PAUL C HODGES and ALEXANDER BRUNSCHWIG Chicago
- The Modified Coutard Technic in Roentgen Therapy (Lantern Demonstration)
J M MARTIN Dallas Texas
- Further Observations on the Diagnosis and Treatment of Carcinoma of the Bladder by the Roentgen Rays (Lantern Demonstration)
G E PFÄHLER Philadelphia
- Radiologic Aspect of Cancer of the Breast from Memorial Hospital (Lantern Demonstration)
FRANK E ADAIR New York
- Roentgen Therapy in Chronic Paranasal Sinusitis A Further Report (Lantern Demonstration)
FRANK E BUTLER and IVAN M WOOLEY Portland Ore

Thursday, June 14—9 a m

- Calcification (Ossification) of Normal Laryngeal Cartilages Mistaken for Foreign Body (Lantern Demonstration)
W EDWARD CHAMBERLAIN and BARTON R YOUNG, Philadelphia
- Arteriography in Peripheral Vascular Disease (Lantern Demonstration)
JOHN D CAMP and E V ALLEN, Rochester Minn
- Differential Diagnosis of the Leukemic States with Particular Reference to the Immature Cell Types (Lantern Demonstration)
ROY R KRACKE Emory University Ga
- Classification and Differential Diagnosis of the Anemias (Lantern Demonstration)
RUSSELL L HADEN Cleveland
- The Relation of Cell Types in Leukemia to Sensitivity to Radiation (Lantern Demonstration)
RAPHAEL ISAACS Ann Arbor Mich
- Diagnosis and Treatment of Various Types of Leukemias (Lantern Demonstration)
NATHAN ROSENTHAL New York

Friday, June 15—9 a m

Election of Officers

- Intrahepatic Gallbladder (Lantern Demonstration)
E P MCNAMEE Cleveland
- Comparison of the Urinary Tract in Pregnancy and Pelvic Tumors (Lantern Demonstration)
EDGAR C BAKER and JOHN S LEWIS JR, Youngstown Ohio
- The Effect of Intracranial Tumors on the Sella Turcica (Lantern Demonstration)
KARL KORNBLUM and LESLIE H OSMOND Philadelphia
- Pulmonary Manifestations in Human Tularemia (Lantern Demonstration)
V W ARCHER and STAIGE D BLACKFORD University, Va
- Interlobar Pleural Effusions (Lantern Demonstration)
B P STIVELMAN New York
- Interpretation of Roentgenographic Pathology in Pulmonary Tuberculosis (Lantern Demonstration)
HENRY K TAYLOR New York
- Early Diagnosis of Fulminating Pulmonary Tuberculosis in Adults Necessity for Repeated Roentgen Examinations (Lantern Demonstration)
FRANKLIN B BOGART Chattanooga Tenn

SECTION ON MISCELLANEOUS TOPICS

MEETS IN NORTH HALL, LOWER LEVEL,
CLEVELAND PUBLIC AUDITORIUM

Session on Forensic Medicine

OFFICERS OF SESSION

- Chairman—LUDVIG HEKTOEN Chicago
Secretary—HARRISON S MARTLAND, Newark, N J
- Wednesday, June 13—2 p m
- Reform of County Government and the Office of Coroner
OSCAR T SCHULTZ, Evanston, Ill
- Discussion to be opened by H R FISHBACK Chicago
- The Office of the Chief Medical Examiner of New York City as a Medicolegal Center CHARLES NORRIS New York
- An Introductory Course in Legal Medicine for Medical Students (Lantern Demonstration)
S A LEVINSON and C W MUEHLBERGER Chicago
- Forensic Application of Serologic Individuality Tests (Lantern Demonstration)
KARL LANDSTEINER, New York
- Discussion to be opened by ALEXANDER S WIENER Brooklyn
- Subdural Hemorrhage (Lantern Demonstration)
TIMOTHY LEARY Boston
- Alcohol and Automobile Accidents (Lantern Demonstration)
HERMAN A HEISE Milwaukee
- Discussion to be opened by ALEXANDER O GETTLER, New York
- The Isolation of Volatile Poisons from Tissues and Their Identification (Lantern Demonstration)
ALEXANDER O GETTLER, New York
- Discussion to be opened by HARRISON S MARTLAND Newark N J
- The Medicolegal Aspect of Silicosis
WILLIAM D McNALLY, Chicago
- Discussion to be opened by HENRY C SWEANY, Chicago
- An Epidemic of Fatal Estivo-Autumnal Malaria Among Drug Addicts in New York City Transmitted by Common Use of Hypodermic Syringe (Lantern Demonstration)
MILTON HELPERN New York
- Discussion to be opened by CHARLES NORRIS New York
- Carbon Monoxide Poisoning (Lantern Demonstration)
HARRISON S MARTLAND, Newark N J

Session on Nutrition

OFFICERS OF SESSION

- Chairman—JAMES S MCLESTER Birmingham Ala
Secretary—WILLIAM S MCCANN Rochester, N Y
- Thursday, June 14—2 p m
- Nutrition and Resistance to Infection (Lantern Demonstration)
S W CLAUSEN New York
- Address (Lantern Demonstration)
H R GEYELIN New York
- Discussion to be opened by JAMES E PAULLIN Atlanta Ga
- Ulcerative Colitis III The Factor of Deficiency States A Clinical Study (Lantern Demonstration)
THOMAS T MACKIE New York
- What Should a Patient with Arthritis Eat (Lantern Demonstration)
WALTER BAUER Boston

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will be located on the Arena Floor of the Auditorium—the floor directly above the Technical Exhibit and general registration desks. The same general arrangement of booths and decorations will be carried out as in former years. Features this year will be the group exhibits sponsored by the fifteen sections of the Scientific Assembly, motion picture programs to be run simultaneously by several sections, symposiums on amebiasis and treatment of burns as joint undertakings by different sections, special exhibits on treatment of eye injuries by the Section on Ophthalmology and on home delivery technique by the Section on Obstetrics, Gynecology and Abdominal Surgery, and special exhibits subsidized by the Committee on Scientific Exhibit.

Admission will be limited to individuals wearing Fellowship or other badges of the convention and to guests to whom special cards of admission have been issued. The exhibit will *not* be open to the public.

SPECIAL EXHIBITS

Exhibit on Encephalitis

The exhibit on encephalitis, with special reference to the 1933 outbreak, is presented by a special committee under the joint auspices of the Committee on Scientific Exhibit of the Board of Trustees of the American Medical Association, and the United States Public Health Service. The committee is composed of James P. Leake, Washington, D. C., Ralph S. Muckenfuss, St. Louis, and Ralph C. Williams, chairman, Washington, D. C.

The exhibit will consist of charts, specimens, talks and demonstrations. It will be presented under four headings as follows:

Epidemiology	J. P. Leake, Washington, D. C. E. A. Musson, Jefferson City, Mo. H. D. Choate, St. Louis
Pathology	H. A. McCordock, St. Louis W. D. Collier, St. Louis Elizabeth Moore, St. Louis
Etiology	R. S. Muckenfuss, St. Louis Charles Armstrong, Washington, D. C. J. E. Smadel, St. Louis
Clinical Features	R. A. Kinsella, St. Louis T. C. Hempelmann, St. Louis G. C. Brown, St. Louis

Exhibit on Nutrition

In conjunction with Symposium on Nutrition conducted by the Section on Miscellaneous Topics, an exhibit on nutrition will be shown in the Scientific Exhibit under the auspices of the Committee on Scientific Exhibit, the Committee on Foods and Hygiene, the Health Magazine. The committee in charge is composed of Walter C. Alvarez, Rochester, Minn., Reginald Fitz, Boston, and P. C. Jeans, Iowa City. A competent corps of demonstrators will be on hand throughout the week. The following subjects will be included: foundation diets, overfeeding diets for the undernourished, reduction diets for the obese, anti-diarrhea diets, anticonstipation diets, and nutrition in different diseases and abnormal conditions. A pamphlet covering these subjects will be distributed at the meeting.

Demonstrations in Pathology

The special demonstrations in pathology will be presented under the direction of Benjamin S. Kline, pathologist, Mount Sinai Hospital, Cleveland, with an advisory committee consisting of A. B. Luckhardt, Chicago, Frank W. Hartman, Detroit, Howard T. Karsner, Cleveland, William Carpenter MacCarty, Rochester, Minn., and J. P. Simonds, Chicago.

Arrangements have been made to secure both surgical and necropsy material from numerous sources and demonstrations in the exhibit booth will be conducted continuously throughout the week. As an additional feature, special demonstrations at stated periods each morning and afternoon will be given on various subjects in a room directly adjoining the exhibit booth with the following pathologists in charge: Howard T. Karsner, Harry Goldblatt, Allen Graham, R. Dominguez, Alan R. Moritz, H. S. Reichle, Anna M. Young, and B. S. Kline.

SECTION EXHIBITS

Section on Practice of Medicine

Section exhibit committee: IRVING S. WRIGHT, chairman, New York, JAMES HAROLD AUSTIN, Philadelphia, WILLIAM J. KERR, San Francisco, EUGENE S. KILGORE, San Francisco, and L. G. ROWNTREE, Philadelphia.

Besides the exhibits sponsored by the Section on Practice of Medicine, the section is cooperating in the Symposium on Treatment of Burns and in the Symposium on Amebiasis and is contributing to the group of exhibits on thyroid diseases. It is also maintaining a motion picture program in an area adjoining the section exhibits, where motion pictures will be run on a definite schedule throughout the week.

ALBERT S. HYMAN, Witham Foundation for the Study and Prevention of Heart Disease, Beth David Hospital, New York. Transthoracic electrocardiography, demonstration of the nine lead hook-up. Exhibit of photographs, charts, records, graphs and models illustrating the historical development of various leads used in electrocardiography, inadequacy of conventional three lead methods in certain types of coronary and myocardial disease, employment of transthoracic leads for diagnosis and localization of infarcted areas of heart muscle, reconstruction of electrodynamic triangle of the heart to conform with three dimensional theory, clinical application of the nine lead hook up with demonstration of normal records from all age groups and exhibition of various myocardial lesions in coronary disease and allied conditions.

N. M. KEITH, H. P. WAGENFR and N. W. BARKER, Mayo Clinic, Rochester, Minn. Diffuse arterial disease with hypertension. Exhibit of (a) clinical data in essential hypertension with differentiation of groups I, II, III and IV, chronic glomerulonephritis with hypertension, hypertension associated with vasospastic phenomena, (b) enlarged photographs of ocular fundi showing characteristic retinal and vascular changes in foregoing groups, (c) photomicrographs of arterioles seen in biopsy of pectoralis major muscle in cases of hypertension, illustrating pathologic change and changes in lumen to wall ratio, (d) photomicrographs of retinal arterioles in above groups.

CLAYTON J. LUNDY and J. TETREV, Rush Medical College of the University of Chicago, Chicago. Clinical classification of ventricular extrasystoles. Exhibit of charts and photographs showing clinical occurrence and experiments on human hearts. Study of selected electrocardiograms, relationships of age, type of heart disease, clinical left and right ventricular strain, acute and chronic, coronary disease, extracardiac extrasystoles, cardiac hypertrophy especially with anemia, electrocardiographic relationships, congenital heart disease, and pulmonary artery stenosis.

WILLIAM P. MURPHY, Peter Bent Brigham Hospital, Boston. Therapeutic effects of intramuscular injections of liver extract. Exhibit of charts illustrating the effects of intramuscular injections of a solution of liver extract on the white blood cells, particularly granulocytes, the blood platelets and hemoglobin in secondary anemia. Two reel film on pernicious anemia, illustrating the diagnosis, treatment and results with special consideration of the use of liver extract by intramuscular injection.

EDWIN E. OSGOOD, CLARICE ASHWORTH and RICHARD YOUNG, University of Oregon Medical School, Portland, Ore. Morphologic hematology, cells of blood and bone marrow in health and disease. Exhibit of colored drawings of cells of blood and bone marrow, arranged in the order of maturity, also a collection of stained smears of blood and bone marrow for microscopic study, the technique of obtaining bone marrow is illustrated.

H. L. SMITH and F. A. WILLIUS, Mayo Clinic, Rochester, Minn. The heart in obesity. Exhibit of gross specimens completely encased in fat varying from one to several centimeters thick, gross sections showing line of demarcation between the fat and the muscle completely obliterated and fat penetrating completely through the walls of the ventricle and into the papillary muscles, gross specimens demonstrating that fat hearts will float on water and normal hearts will sink, colored photo

micrographs demonstrating how fat has completely penetrated the wall of the ventricles, photographs of injected specimens showing the great vascularity of adipose tissue photomicrographs of perfused, injected and isolated heart of rabbit showing size, distribution and the enormous capillary bed of a normal heart

CARL R. STEINKE, CLARENCE L. HYDE and Associates, Springfield Lake Sanatorium East Akron Ohio Treatment of pulmonary tuberculosis, showing examples of various types of treatment Exhibit of roentgenograms showing results of types of treatment separately and in various combinations of results, as follows 1 Rest cure 2 Pneumothorax 3 Phrenicectomy 4 Paraffin fill 5 Pressure bag 6 Pneumolysis 7 Thoracoplasty

IRVING S. WRIGHT, A. WILBUR DUNEE, JOSEPH KOVACS, DEAN MOFFAT and JOSEPH WIENER, Vascular Clinic, New York Post-Graduate Medical School and Hospital of Columbia University, New York Peripheral vascular circulation, effects of tobacco and certain vasodilators Exhibit of charts and other material demonstrating the effects of tobacco smoking on the peripheral vascular system effects of choline derivatives, especially acetyl-B methyl choline chloride, by various routes of administration, method of treatment

WALLACE M. YATER and V. H. CORNELL, Army Medical Museum, Washington, D. C. Lesions of the conduction system of the heart Exhibit of colored plaques of microscopic sections through the conduction system at various levels Photographs of salient electrocardiograms, roentgenograms gross cardiac lesions and microscopic sections are shown of several cases of auriculoventricular and bundle branch block

Motion Pictures—The following motion pictures will be shown on a definite schedule, to be announced later

CLAYTON J. LUNDY, Chicago "The Normal Heart Beat Cycle"

WILLIAM P. MURPHY, Boston "Pernicious Anemia Diagnosis, Treatment and Results"

S. A. WEISMAN, Minneapolis, Minn. "Is the Tuberculous Chest Flat?"

Section on Surgery, General and Abdominal

Section exhibit committee ALTON OCHSNER chairman New Orleans, and W. L. ESTES JR., Bethlehem, Pa.

In addition to the exhibits sponsored by the Section on Surgery, General and Abdominal, the section is cooperating in the Symposium on Treatment of Burns and is taking charge of the motion picture program for that symposium

CLAUDE S. BECK, Western Reserve University School of Medicine and Lakeside Hospital Cleveland Circulatory failure produced by compression of the heart, curable by operation Exhibit of photographs, drawings, charts and motion picture illustrating physiology, pathology, clinical manifestations, operative procedures, and results in cases of cardiac compression A new conception of pericardial disorders is presented and a new clinical nomenclature is advocated

HARRY E. MOCK, A. R. MORROW and C. E. SHANNON, Northwestern University School of Medicine, Surgical Department, and St. Luke's Hospital Chicago Skull fractures and cerebral injuries Exhibit of plaster models, charts and photographs illustrating skull fractures and cerebral injuries

PENN. RIDDLE, Baylor University College of Medicine, Dallas Texas Are peptic ulcers varicose ulcers? Exhibit of models and drawings showing varicose ulcers of the leg and peptic ulcers, illustrating their relation to the portal system of veins, augmented by a motion picture

CLAIRE L. STRAITH, Detroit Reconstructive facial surgery Exhibit of enlarged photographs and models illustrating various points in technique and results accomplished in the treatment of facial deformities particular attention being paid to treatment of facial wounds and facial bone injuries due to motor accidents

J. ROSS VEAL and URBAN MAES, Department of Surgery, Louisiana State University Medical Center New Orleans Arteriography with thorium dioxide solution (stabilized) in peripheral vascular diseases Exhibit of a number of selected arteriographs demonstrating various peripheral circulatory diseases such as angiospasm gangrene of various types Buerger's

disease, extravascular tumors and varicose veins, there will be included also one arteriovenous aneurysm of the femoral vessels and one popliteal aneurysm

CHARLES S. WHITE, GEORGE B. JENKINS and J. LLOYD COLLINS, George Washington University School of Medicine, Department of Surgery and Anatomy, Washington, D. C. Innervation of muscles of anterior abdominal wall Exhibit of illustrations from dissections and operations

Section on Obstetrics, Gynecology and Abdominal Surgery

Section exhibit committee E. D. PLASS, chairman, Iowa City, ARTHUR H. BILL, Cleveland, and WILLIAM H. WEIR, Cleveland

A special feature of the Section on Obstetrics, Gynecology and Abdominal Surgery will be an exhibit on home delivery technic, presented by the section exhibit committee A motion picture program will be run in a space adjoining the exhibit

SPECIAL EXHIBIT SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY Home delivery technic A slum bedroom will be set up with the usual minimum amount of furniture Demonstrations will be carried on each day on a definite schedule under the direction of the Obstetrical Department of Johns Hopkins Hospital, Baltimore, St. Louis Maternity Hospital Maternity Hospital of Cleveland, Chicago Lying-In Hospital and Chicago Maternity Center

LLOYD ARNOLD and C. J. GUSTAFSON, University of Illinois College of Medicine Chicago Normal menstruation Exhibit of graphs, charts and colored drawings illustrating (1) periodicity, (2) duration, (3) grams of exudate, (4) percentage of blood in exudate in normal females from 12 to 50 years of age over a period of years

E. C. HAMBLEN and ROBERT A. ROSS, Department of Obstetrics and Gynecology, Duke Hospital, Durham, N. C. Studies of endometrial and ovarian responses in women to extracts of pregnancy urine Exhibit of case summaries, photomicrographs of endometrium before and after administration of extracts photomicrographs of portions of ovaries removed and studied after serial sectioning, and charts illustrating results obtained in several years of study of endometrial and ovarian responses to extracts of pregnancy urine administered preoperatively These studies were made primarily in patients with hyperplasia of the endometrium

WILLIAM C. LANGSTON and BYRON L. ROBINSON, University of Arkansas School of Medicine, Little Rock, Ark. Castration atrophy and theelin Exhibit of microscopic sections charts and tables showing (1) effect of double ovariectomy on the rat uterus as to chronology, degree, location and histologic changes associated therewith (2) effect of theelin as a restorative of atrophic rat uteri, (3) duration of effect of theelin as a restorative of atrophic uteri following double ovariectomy In all experiments, opposite horns were used as controls

T. O. MENEES and J. D. MILLER, Blodgett Memorial Hospital, Grand Rapids, Mich. Demonstration of the endometrium by thorium hydroxide solutions Exhibit of roentgenograms obtained by intra-uterine injection of thorium hydroxide solutions, including normal variations in the endometrium of the menstrual cycle, hyperplasia, endometrioma, polyps, retained products, submucous fibroids and carcinomas, accompanied by some gross specimens

GILBERT P. POND, West Suburban Hospital, Oak Park, Ill. A new and positive method of identification of new-born infants Exhibit of palm printing outfit for infants and adults series of typical prints, demonstration of classification methods, files, and charts illustrating types of palm patterns

HENRY SCHMITZ and HERBERT E. SCHMITZ, Loyola University School of Medicine Chicago Early diagnosis, clinical grouping and indications of various methods of treatment of carcinoma of uterine cervix Exhibit of charts illustrating and describing clinical observations, diagnosis of extent of tumor indications for various methods of treatment, and technic of radiation therapy

Motion Pictures The following motion pictures will be shown on a definite schedule to be announced later

JOSEPH B. DELEE, Chicago "Safeguarding Motherhood"

Section on Ophthalmology

Section exhibit committee THOMAS D ALLEN, chairman, Chicago, PARKER HEATH, Detroit, and A D RUEDEMANN, Cleveland

A special exhibit of the Section on Ophthalmology on First Aid in Eye Injuries will be presented under the auspices of the section exhibit committee

SPECIAL EXHIBIT, SECTION ON OPHTHALMOLOGY First aid in eye injuries Exhibit will cover eye injuries in birth, in preschool age, in school age, in adults, in industry, in rural communities, the value of the roentgen ray in eye injuries, and a summary of preventive measures The following ophthalmologists will demonstrate Thomas D Allen, Hallard Beard, Vernon L Leech, Leo L Mayer, Samuel J Meyer, Sydney Walker and George H Woodruff A pamphlet giving essential factors concerning first aid will be distributed

JOHN E L KEYES, Laboratory of Anatomy, Western Reserve University, Cleveland Optic foramen in the dried human skull Exhibit of photographs illustrating (1) normal optic foramen, (2) variations in the contiguous sinuses, (3) foramen for the internal carotid artery adjoining the optic canal, (4) separate foramen for the ophthalmic artery, (5) interclinoid bridges, (6) unusual apertures and walls of the optic foramen, (7) relationship of the long axis of the optic foramen to various planes of the skull Prints of roentgenograms illustrating (a) the foregoing aberrations, (b) foramina roentgenographed (1) directly along the axis of their canals, (2) a known number of degrees off that axis, (3) from the outside of the skull, as in the living subject

WILLIAM F MONCREIFF and BERTHA KLIEN, Rush Medical College, University of Chicago, Chicago Lesions of the fundus oculi Exhibit of paintings and photographs showing histopathologic changes and ophthalmoscopic details in lesions of the following structures (1) retina, including retinal vessels and macular area, (2) choroid, (3) optic papilla Classified from the clinical and pathologic points of view, the following groups of lesions of the fundus oculi are presented (1) congenital anomalies, (2) inflammatory processes, (3) degenerative processes, (4) injuries, (5) neoplasms

GEORGE H STINE, Colorado Springs, and CLIFFORD B WALKER, Los Angeles Intra-ocular localization and treatment of separated retina Exhibit of diagrammatic charts showing the course of light rays from the retinal tear outward through the pupil by way of the nodal points and pupils of entrance and exit, method of determining the limbus distances to the retinal lesion from the angular position in the field of vision as found on the perimeter

PHILLIPS THAGESON, University of Iowa, Iowa City Laboratory diagnosis of certain conjunctival diseases, including etiology of inclusion blennorrhea Exhibit of cultures, slides and colored drawings illustrating the essential points in the laboratory diagnosis of the following pneumococcal conjunctivitis, staphylococcal conjunctivitis, chronic pseudomembranous conjunctivitis, Morax-Axenfeld conjunctivitis, Koch-Weeks and influenza bacillus conjunctivitis, trachoma gonorrheal ophthalmia, spring catarrh and inclusion conjunctivitis of the new-born and the adult

Section on Laryngology, Otology and Rhinology

Section exhibit committee WILLIAM V MULLIN, chairman, Cleveland AUSTIN A HAYDEN, Chicago, and JOHN J SHEA, Memphis, Tenn

CHEVALIER LAWRENCE JACKSON and ALBERT K MERCHANT Temple University Hospital Philadelphia Hiatal hernia of the stomach differential diagnosis from "cardiospasm," peptic ulcer, cicatricial stenosis and carcinoma of the esophagus Exhibit of transparencies showing roentgenographic and endoscopic appearances and histopathology illustrating differential diagnosis of diseases of the lower esophagus, particular attention being paid to hiatal hernia of the stomach

MYRON METZENBAUM, Cleveland Asymmetry of the nares and dislocation of the lower end of the septal cartilage in the new-born and in young children Exhibit of mounted photographs and casts, and a mechanically operated model demonstrating the foregoing subjects

CLAUDE MOORE, George Washington University Hospital, Washington, D C Tumors, polyps and cysts in the nasal accessory sinuses Exhibit of roentgenograms showing tumors, polyps and cysts in the nasal sinuses A large number of cases proved by iodized oil injection with roentgenologic examination, with clinical data, operative procedures and other information

WILLIAM V MULLIN and W L DEETON, Department of Otolaryngology, Cleveland Clinic, Cleveland Comparative study of the larynx Exhibit of a study of the larynx by wax models of the interior and exterior of the larynx of animals, reptiles and birds

Section on Pediatrics

Section exhibit committee F THOMAS MITCHELL, chairman, Memphis, Tenn, W C FARGO, Cleveland, and ABRAHAM LEVINSON, Chicago

H H DONNALLY and MARGARET M NICHOLSON, George Washington University School of Medicine, Washington, D C Smallpox vaccination of new-born infants Exhibit of colored life size drawings of three types of takes, charts and tables relating to methods of securing takes and covering a study of vaccination of a large number of new-born infants

J M FRAWLEY, Fresno, Calif The prophylaxis of whooping cough Exhibit demonstrating the preparation of pertussis antigen, showing the various stages from the time the cough plates are taken until the antigen solution is ready for use, charts showing the value of prophylactic vaccination

HENRY J GERSTENBERGER, A J HORESH, J D NOURSE, G R RUSSELL, A L VANHORN, DONALD N SMITH, CATHARINE ROSE, EDNA CHAPMAN and DAVID SHIELDS, Babies and Childrens Hospital, Cleveland Tungsten filament radiation (dual purpose lighting) Exhibit of (a) photographs illustrating the manner of exposure of wetnurses, orphanage children and rachitic infants to ceiling lights, (b) graphic charts showing diet, blood calcium and phosphorus levels of rachitic infants before and during the observation period, (c) roentgenograms of wrists of infants, showing rate and extent of healing, (d) roentgenograms showing effect of feeding rats a rachitic diet to which the blood from the exposed wetnurses and orphanage children has been added

ARCHIBALD L HOYNE and JOHN HAYS BAILEY, Municipal Contagious Disease Hospital, Chicago The secondary case of scarlet fever Exhibit of china figures, charts, diagrams and graphs showing the origin of secondary cases of scarlet fever from hospitalized cases the complication present in both primary and secondary cases and the effect of various quarantine regulations on the secondary scarlet fever rate

J ARTHUR MYERS Lymanhurst School and University of Minnesota, Minneapolis Tuberculosis in chests of children and young adults Exhibit of roentgenograms of chests of children which show the development of the first infection type of tuberculosis from the acute inflammatory stage to the formation of calcium deposits Reinfection type of disease is also demonstrated from its earliest detectable stage to cavity formation Various types of lesions and results of treatment are shown by roentgenograms

FRANK VANDER BOGERT, Department of Pediatrics, Ellis Hospital, Schenectady, N Y Study in infant stools Exhibit of a collection of mounted plasticine models of infant stools from actual normal and abnormal specimens, showing the effects of various types of feeding and of changes in the constituents of the formulas

Section on Pharmacology and Therapeutics

Section exhibit committee RUSSELL L HADEN chairman, Cleveland A CARLTON ERNSTENE, Cleveland, and CARL H GREENE, New York

The Section on Pharmacology and Therapeutics is contributing to the Symposium on Amebiasis in addition to the exhibits listed below

FRANKLIN J BACON, Western Reserve University School of Pharmacy, Cleveland Cultivation of medicinal plants Exhibit of pictures mounted specimens and potted plants cultivated by the School of Pharmacy at Squire Valleevue Medicinal Plant Garden, demonstration of manufactured products from plants grown

O W BARLOW and J L JONES, Departments of Pharmacology and Obstetrics, Western Reserve University School of Medicine, Cleveland Charts and apparatus showing records of the actions of ergot

C K HINNELSBAUGH, United States Public Health Service, Fort Leavenworth, Kansas, and G H GERLACH and E J STANTON, Department of Pharmacology Western Reserve University School of Medicine, Cleveland Method of testing morphine, codeine and diacetylmorphine habituation in rats Exhibit of apparatus tracings and charts showing the trend of struggle response exhibited during habituation to and withdrawal from morphine, codeine and diacetylmorphine

W E LOWER, E L WALSH and D ROY McCULLAGH Cleveland Clinic Foundation, Cleveland Experimental investigation of testicular extracts (a) Exhibit of mounted specimens, wax models and diagrams demonstrating parabiosis in rats, demonstration of prostatic hypertrophy and atrophy in rats (b) Wax models and diagrams showing effects of castration on other endocrine organs and the influence of various injections on these changes (c) Diagrams showing the effect of injections of male sex hormone in normal rats

(a) TORALD SOLLMANN Department of Pharmacology Western Reserve University School of Medicine Cleveland Studies on optical projection of excised organ activity in the frog heart (b) TORALD SOLLMANN, H N COLE, N E SCHREIDER and K I HENDERSON, Department of Dermatology, Western Reserve University School of Medicine, Cleveland Charts illustrating excretion studies of mercury and bismuth

Section on Pathology and Physiology

Section exhibit committee WILLIAM CARPENTER MACCARTY, chairman, Rochester, Minn., FRANK W HARTMAN, Detroit, A B LUCKHARDT, Chicago, and J P SIMONDS, Chicago

In addition to the exhibits listed below the Section on Pathology and Physiology is cooperating in the Symposium on Treatment of Burns and in the Symposium on Amebiasis and is contributing to the group of exhibits on thyroid diseases The section exhibit committee is also acting in an advisory capacity concerning the special demonstrations in pathology

L W DREES, Department of Clinical Pathology, University of Tennessee, Pathological Institute Memphis, Tenn Sick cell anemia Exhibit of (1) series of photographs, photomicrographs and drawings showing the appearance of patients with sick cell anemia the leg ulcers, the blood picture the pathologic changes and the roentgen observations, (2) printed matter giving a word picture of the disease under etiology incidence, history, physical examination laboratory observations, pathology prognosis and treatment, (3) microscopes to demonstrate blood smears, moist preparations and pathologic sections

CHESTER W EMMONS College of Physicians and Surgeons Columbia University, New York Morphologic basis for a simplified classification of the dermatophytes Exhibit of cultures of different types of dermatophytes of photographs of cultures photomicrographs and drawings of significant morphologic features, keys and explanatory material

RUSSELL L HADEN Cleveland Clinic Cleveland 1 Exhibit of charts and apparatus to illustrate the complete laboratory examination of the blood and methods of calculation 2 Natural color photomicrographs of all types of blood cells and various blood dyscrasias

REUBEN L KAHN University of Michigan Hospital Ann Arbor, Mich Studies on tissue reactions in immunity Exhibit of charts showing quantitative measurements of skin reactions in specifically immunized animals, relation between skin reactions and serum reactions specific reacting capacities of various tissues, desensitization (disimmunization) and associated phenomena

ROY R KRACKE and FRANCIS P PARKER Emory University School of Medicine, Atlanta, Ga The etiology of granulopenia (agranulocytosis) Exhibit of charts tables graphs and diagrams illustrating the incidence of granulopenia in nurses physicians and physicians families studies bearing on geographic distribution and on the incidence as related to the administration of certain types of drugs with evidence that the disease is caused by the administration of certain benzene con-

taining drugs and barbiturates, records of animal experiments showing effect of these drugs in rabbits and guinea-pigs

ALAN R MORITZ, Department of Pathology, Western Reserve University, Cleveland Ovarian tumors Exhibit of a series of translucent photographs showing gross and microscopic structures of tumors of the ovary

VICTOR C MYERS E MUNTWYLER, F C BING, R F HANZAL and C T WAY, Western Reserve University School of Medicine, Cleveland Biochemical diagnostic methods Exhibit of practical demonstrations of simple clinical procedures in biochemical diagnostic methods A regular schedule of demonstrations will be run each day

HERBERT S REICHEL, HOWARD T KARSNER and THOMAS T FROST, Institute of Pathology, Western Reserve University School of Medicine, Cleveland Typical forms of tuberculous pulmonary disease Exhibit of transilluminated photographs of coronal sections of the lungs fixed in situ illustrating pathogenesis of tuberculous infection and demonstrating morphologic bases of the more common types of tuberculous pulmonary disease

JANE SANDS ROBB and J F FRED HISS, Syracuse University College of Medicine, Syracuse, N Y Cardiac muscles Exhibit of human hearts dissected to show the component muscles, similar dissections of dog hearts, colored plaster casts of dissections, preparations of injected coronary vessels, charts and tracings showing typical changes in electrocardiogram when an individual muscle is eliminated

GEORGE C SHIVERS, University of Colorado Medical School, Colorado Springs Avoidance of pulmonary embolism from intravenous arsenicals Exhibit of tissue, slides, photographs, charts and test tube experiments, demonstrating (a) a fatal case of pulmonary embolism from an intravenous arsenical (b) the frequency of such accidents, (c) the cause of such embolism to be a change in the pH value of the drug with a resultant precipitation of the drug in the blood stream, (d) method devised for the prevention of pulmonary embolism from intravenous arsenicals

GREGORY SHWARTZMAN Mount Sinai Hospital, New York Phenomenon of local skin reactivity to bacterial filtrates Exhibit of charts diagrams, lantern slides, microscopic slides moulages, living animals and preserved specimens illustrating the appearance and nature of the phenomenon, its role in immunology in relation to other immunologic processes, new types of toxins and antitoxins and practical applications to treatment of typhoid fever, meningococcal meningitis and nonspecific ulcerative colitis

MARGARET WARWICK, Millard Fillmore Hospital, Buffalo The necropsy in the general hospital, as interpreted at the Millard Fillmore Hospital Exhibit of posters and photographs showing the importance and the availability of the necropsy to the general hospital, and methods of overcoming the usual objections

Section on Nervous and Mental Diseases

Section exhibit committee GROVES B SMITH, chairman, Godfrey Ill., THOMAS J HELDT, Detroit, and LLOYD ZIEGLER, Albany, N Y

A W ADSON W McK CRAIG, J G LOVE, H W WOLTMAN, F P MOERSCH, H L PARKER, W D SHELLEN and J W KERNOHAN, Mayo Clinic and Mayo Foundation Rochester Minn Neurologic diseases and neurosurgical procedures Exhibit of moulages showing technic of some of the more important operations on the brain and cord, transparencies, photomicrographs, abstracts of histories, and motion pictures illustrating various parts of a neurologic examination and some operations

MAX A BARR and WALTER L BRUETSCH, Central State Hospital and Department of Mental and Nervous Diseases, Indiana University School of Medicine Indianapolis Malarial treatment of dementia paralytica Exhibit of transparencies showing the activation of the histiocytes (plasmatocytes, macrophages) in the brain, liver, spleen and bone marrow during the malaria treatment, comparative study of stimulating phagocytosis with malaria plasmodia streptococci and other organisms, the blood picture of therapeutic malaria, the dangers of

the malaria treatment, the histopathology of untreated and malaria-treated dementia paralytica, the influence of therapeutic malaria on the ocular manifestations in dementia paralytica, serologic histories of malaria-treated patients with dementia paralytica

WALLACE B HAMBY and W JAMES GARDNER, Cleveland Clinic, Cleveland Intracranial neoplasms Exhibit of charts illustrating various types of intracranial tumors, each with patient's history, physical observations, data of special examinations, notes and photographs of operations, together with a summary of the type pathology

HARRY D PIERCE and LOUIS J KARVOSCH, Cleveland Cerebrospinal fluid hydrodynamics, with a demonstration of encephalography and graphic methods of recording pressure phenomena Exhibit of 1 Practical demonstration of encephalography done by the closed methods, a manikin constructed to show how displacement occurs 2 Manikin with the Trattner hydrophorograph attached to needles in the cistern and lumbar locus demonstrating how permanent graphic records are obtained in subarachnoid block tests 3 Illuminated box showing different conditions recorded by such methods which have important diagnostic significance 4 Encephalographic studies

Section on Dermatology and Syphilology

Section exhibit committee FRID D WEIDMAN, chairman, Philadelphia, CLARK W FANNERUP, Chicago, ROBERT L GILMAN, Philadelphia and JOHN E RAUSCHKOLB, Cleveland

Symposium on Cutaneous Allergy MARION B SULZBERGER and FRED WISE, New York Post-Graduate Medical School of Columbia University, New York Allergic Dermatoses (illustrating paper by Alfred F Coca to be read before the Section on Dermatology and Syphilology) Exhibits by NELSON PAUL ANDERSON and SAMUEL AYRES JR Los Angeles Observations on light sensitive dermatoses and by LOUIS A BRUNSTING and C R ANDERSON Mayo Clinic, Rochester, Minn Ragweed dermatitis, illustrate papers which they will read before the Section on Dermatology and Syphilology

Authors' Exhibits The following exhibits illustrate papers to be read before the Section on Dermatology and Syphilology

THEODORE CORNBLEET and M A KAPLAN University of Illinois College of Medicine, Chicago Urinary proteose in eczema Exhibit of materials isolated and placards giving the essential results of their use in skin tests therapeutic trials and immunologic studies in rabbits

NORMAN EPSTEIN and MAURICE COHEN Mount Zion Hospital, San Francisco The use of hyperpyrexia in the treatment of syphilis Exhibit of photographs illustrating method of carrying out treatment temperature charts and graphic illustrations of results

GEORGE M LEWIS and DAVID L SATFENSTEIN New York Post-Graduate Hospital, New York Spiegler Fendt sarcoid Exhibit of clinical photographs, photomicrographs and diagrams illustrating the Spiegler-Fendt sarcoid

JAMES HERBERT MITCHELL, Rush Medical College, Chicago Exhibit of photographs illustrating streptococcal infections simulating ringworm of the hands and feet

SAMUEL M PECK, NATHAN ROSENTHAL and HAROLD A ABEL, Mount Sinai Hospital, New York Snake venom therapy in hemorrhagic diathesis Exhibit of colored drawings and pictures of skin manifestations following injections of venom Schwartzman phenomenon, pictures of the different types of snakes, exhibit of charts and graphs demonstrating clinical effects of venoms

MAURICE J STRAUSS and MARION E HOWARD Yale University Medical School and New Haven Hospital, New Haven, Conn The Frei test for lymphogranuloma inguinale Recovery of the antigen from a strongly positive test Exhibit of charts showing results of experiments photographs and lantern slides of the test

FRED D WEIDMAN and JACQUES P GUEQUIERRE, University of Pennsylvania Philadelphia High frequency currents in performing biopsies Exhibit demonstrating that electric currents may produce such a wide zone of coagulation necrosis

around biopsy specimens as to interfere with histologic study Data indicate how wide such a zone of coagulation necrosis may be with different coagulating and cutting currents, it is also indicated how small a specimen may be removed by such technique and still preserve sufficient noncoagulated tissue for histologic study

ASHTON LEROY WEISS, Mayo Foundation, Rochester, Minn Pemphigus Exhibit of photographs of experimental lesions in animals and man, charts illustrating agglutination, absorption agglutination, precipitin fermentation, cataphoretic velocity, serum potential absorption serum potential, and serum potential studies of pemphigus and control serum, photographs of organisms, and charts illustrating some of the characteristic properties of the organism

ERWIN P ZEISLER and MARCUS R CARO, Chicago Necrobiosis lipoidica diabetorum Exhibit of colored photographs and photomicrographs illustrating clinical appearance and histologic observations

Independent Exhibits The following exhibits are independent of the symposium and the authors' papers

PAUL BICHET, New York Exhibit of photographs and charts illustrating hereditary dermatoses diagrams showing lines of transmission through different generations

H N COLE and J R DRIVER, Department of Dermatology, Western Reserve University School of Medicine, Cleveland Treatment of malignant conditions of the skin and mucous membranes Exhibit of transparent photographs and photomicrographs illustrating the modern trend in the treatment of malignant conditions of the skin and mucous membrane The technique and results of treatment by the interstitial use of heavily filtered radium needles of small intensities is featured

R L MCINTOSH and M E DIEMER, University of Wisconsin, Madison, Wis Delochrome prints Exhibit of Delochrome prints from a large collection of photographs of living patients with dermatologic diseases, to illustrate the adaptability of these prints to photographing dermatologic conditions, to bring out the minute variations and details so essential in dermatologic diagnosis

MARTIN SNIDERMAN, Department of Dermatology, University of Pittsburgh, Pittsburgh Exhibit of moulages illustrating actual dermatologic conditions

ERWIN P ZEISLER and MISS ESTHER BOHLMAN, Michael Reese Hospital, Department of Dermatology, Chicago Exhibit of colored photographs of skin and mucous membrane lesions selected for their value for teaching purposes

Section on Preventive and Industrial Medicine and Public Health

Section exhibit committee PAUL A DAVIS, chairman, Akron, Ohio ALICE HAMILTON, Boston, THURMAN B RICE, Indianapolis, and THEODORE L SQUIRE, Milwaukee

The Section on Preventive and Industrial Medicine and Public Health is cooperating in the Symposium on Amebiasis in addition to the following exhibits

EMILY DUNNING BARRINGER, HANAN STRAUSS, D F CROWLEY, in collaboration with ANNA W WILLIAMS, ANNIS THOMSON and ARCHIBALD McNEIL, Kingston Avenue Hospital, New York Differential diagnosis of gonorrhea in the female Exhibit demonstrating differential diagnosis of gonorrhea in the female, symptoms and laboratory tests differentiating gonorrhea from other inflammatory diseases of the female genital tract, especially due to Actinomyces

LOUIS I DUBLIN Metropolitan Life Insurance Company, New York Progress in public health since 1900 Exhibit of charts showing past and present public health problems, the fight against diseases, the gains in chances of survival

R R JONES United States Public Health Service, Washington, D C The lead hazard in industry and its control Exhibit of charts and graphs showing the extent of lead compounds most commonly used and the solubility in the body fluids, recognized procedure for the control of industrial plumbism, demonstration of sampling apparatus by measuring the lead content in the atmosphere demonstration and test for lead in human excreta and demonstration of blood films showing changes typical of plumbism

THURMAN B RICE and VIRNE K HALVEY, Indiana University and Indiana Division of Public Health, Indianapolis The "Indiana Plan" of health work coordination Exhibit of plans, charts and maps showing the work of the new division of public health in Indiana

Section on Urology

Section exhibit committee RUSSELL S ILLGUSON, chairman, New York, THOMAS D MOORE, Memphis, Tenn., and MOSES SWICK, New York

The exhibits of the Section on Urology will fall into three groups, to correspond with the three symposiums to be considered by the section in the Scientific Assembly

LAWRENCE N ATLAS and CHARLES A BOWERS Department of Urology, St Luke's Hospital, Cleveland Methods for teaching basic urology Exhibit of lead molds of different types of normal and abnormal kidney pelvises together with their respective pyelograms, plaster reproductions of variations in the anatomy of the dissected hilus of normal and pathologic kidneys, and of pathologic bladder necks

A ELMER BELT and DONALD A CHARNOCK, Los Angeles Urinary calculi Exhibit of urinary calculi with graphic illustrations concerning formation, classification, diagnosis and treatment

HUGH CABOT, WALTER WALTERS V S COUNSELLER and J T PRIESTLEY, Division of Surgery, and W F BRAASCH Division of Urology Mayo Foundation, Rochester Minn Operative treatment of stones in the kidney Exhibit of (1) motion picture of operative technique in removal of renal stones, (2) continuous lantern projector showing slides on surgical management factors of safety and illustrative cases (3) stationary displays on general management of a large number of cases of nephrolithiasis factors predisposing to calculus formation postoperative treatment chemical composition of stones, exhibit of stones and special features regarding bilateral and recurrent renal stones and display of specimens

CHARLES C HIGGINS, Cleveland Clinic, Cleveland Experimental production and solution of urinary calculi Exhibit of roentgenograms demonstrating experimentally formed renal and bladder stones in rats under vitamin A deficiency, charts showing incidence of renal and bladder infection in rats under vitamin A deficiency diet and frequency of stones at intervals during the experiment Roentgenograms of clinical cases demonstrating the decrease in size of the renal calculi when patient is placed on a special diet high in vitamin A

FREDERICK LIEBERTHAL Department of Urology, Michael Reese Hospital, Chicago Special pathology of renal tuberculosis Exhibit of drawings and charts of a study of a large number of cases of renal tuberculosis depicting the development of the disease from the earliest states to complete destruction of the kidney

LELAND M MCKINLAY Grand Rapids, Mich Nerve control of the urinary bladder, mechanical demonstration Exhibit of a life size model of a male torso connected electrically and mechanically so that the complete act of urination is enacted to illustrate the response of the urinary bladder and sphincters to impulses coming over the sympathetic and parasympathetic nerves and the coordinated contraction or relaxation of the internal and external sphincters A series of cystometrograms is presented to demonstrate the variations in intracystic pressure subsequent to the use of sympathetic and parasympathetic nerve stimulants

W CALHOUN STIRLING Washington D C Carcinoma of the prostate gland Exhibit of photographs and specimens showing incidence latest methods of diagnosis symptoms differential diagnosis, gross and microscopic anatomy associated gross lesions and all forms of latest recognized therapy

G J THOMPSON and J T PRIESTLEY Mayo Clinic, Rochester, Minn Transurethral prostatic resection Exhibit showing the type of case encountered method of preliminary preparation technique of operation and postoperative care including complications, and necropsy material Special emphasis will be placed on technique and methods employed to prevent complications

Section on Orthopedic Surgery

Section exhibit committee E B MUMFORD chairman Indianapolis, PAUL N JEPSON, Philadelphia, and J T O'FERRALL, New Orleans

WALTER BAUER and GRANVILLE A BENNETT, Departments of Medicine and Pathology, Harvard Medical School and Medical Clinic of Massachusetts General Hospital, Boston Degenerative changes in joints resulting from continued trauma and increasing age and their relationship to hypertrophic arthritis Exhibit of charts photographs, roentgenograms, gross specimens and microscopic sections, illustrating the repair of articular cartilage and the effects of patellar displacement together with changes resulting from unusual and continued trauma

MICHAEL S BURMAN, LEO MYER and HARRY FINKELSTEIN, Hospital for Joint Diseases, New York Arthroscopy the direct visualization of joints Exhibit of paintings, photographs and charts showing the summation of numerous cases in which arthroscopy was used

ALBERT B FERGUSON and M BECKETT HOWARTH New York Orthopedic Dispensary and Hospital, New York Coxa plana and related conditions at the hip Exhibit of prints, diagrams and microscopic slides demonstrating the etiology, pathology and relations of coxa plana, slipping of the upper femoral epiphysis osteochondritis dissecans, arthritis and a condition, designated coxa magna, characterized by enlargement of the femoral head and neck

EDSON B FOWLER, Department of Anatomy, Northwestern University Medical School, Chicago Absorbable horn fixation of fractures Exhibit of (1) many long human bones fractured to illustrate various kinds and location of breaks and held with horn by simplified method of internal fixation (2) horn in stages of preparation and sizes of stock needed in different bones, (3) new fracture instrument for reduction and bone reamers that simplify the technique, (4) roentgenograms of several cases of fractures before and after, with end results (5) specimen of horn fixation of fractured dog's ulna showing union and partial absorption of the horn

BAYARD T HORTON Mayo Foundation Rochester, Minn Congenital arteriovenous fistula of the extremities Exhibit of photographs, wax casts roentgenograms arteriograms and photomicrographs illustrating clinical, physiologic and pathologic studies of a series of cases of congenital arteriovenous fistula of the extremities

CHARLES N PEASE Children's Memorial Hospital, Chicago Injuries to the vertebrae and intervertebral disks following lumbar puncture Exhibit of sketches showing the intervertebral disk and vertebrae normal and when spine is flexed showing increasing intradisk pressure and herniation into neural canal roentgenograms of actual cases, mounted gross specimens showing needle pushed into disk and into vertebral body, photographs of vertebrae and disks, enlargement of lumbar spine with accompanying photomicrographs A large model of the lumbar spine and intervertebral disks made out of wood showing what happens when needle is introduced too far

R PLATO SCHWARTZ University of Rochester School of Medicine and Dentistry Rochester, N Y Muscle function and gait as recorded by the electrobasograph Exhibit presenting (1) the demonstration of a method of obtaining records of the function of certain muscles during walking (2) records that will give graphic evidence of the improvement in function of locomotion following treatment for various causes of disability in function of the lower extremities (3) records that will show the influence of various types of shoes on feet with different physical characteristics

FRED J WANPLER Medical College of Virginia, Richmond, Va and J PRESTON MAXWELL Peiping Union Medical College, Peiping China Osteomalacia Exhibit of slides and charts illustrating (a) the principal causes of the disease (b) early symptoms (c) facts obtained in a study of a number of Chinese women, charts showing fetal rickets and pictures relative to the disease

Section on Gastro-Enterology and Proctology

Section exhibit committee A H AARON, chairman, Buffalo, WALTER FANSLER, Minneapolis, and VERNON C ROWLAND, Cleveland

The Section on Gastro-Enterology and Proctology is giving special attention to the Symposium on Amebiasis, in addition to the following exhibits

BURRILL B CROHN and LEON GINZBURG, Mount Sinai Hospital, New York Regional ileitis Exhibit of slides showing histologic structure of inflammatory lesion, charts showing distribution of inflammatory granulomas in ileum and contrasting benign involvements of colon, or colon and ileum in colitis and the dysenteries

THOMAS E JONES, Cleveland Clinic Foundation, Cleveland Carcinoma of colon and rectum Exhibit of wax models showing malignant growths of the colon, chiefly of the rectum, removed by abdominal perineal method

JOHN L KANTOR, New York Regional (terminal) ileitis Exhibit of prints of roentgenograms illustrating diagnostic and differential diagnostic criteria on regional ileitis

LAY MARTIN, Johns Hopkins University, Baltimore Studies on the physiologic chemistry of gastric secretion Exhibit of charts demonstrating normal and pathologic states of gastric secretion tubes containing organic and inorganic materials microscopic demonstrations of crystallized gastric proteins and osazones

HENRY A RAFSKY, From the Max Einhorn Gastro-Enterological Clinic, Lenox Hill Hospital New York Stomach lavage microscopy as a diagnostic aid in biliary tract disease Exhibit of a study of a group of patients with and without biliary tract disease Photomicrographs of crystals observed in lavage water before operation compared with photomicrographs of crystals seen in the bile and stones removed from the gall-bladder or bile ducts at operation will be shown

CURTICE ROSSER and LEWIS WATERS, Baylor University, Department of Medicine Sections on Proctology and Medical Art, Dallas, Texas Anal tumors and rectal foreign bodies Exhibit of illuminated photographs, photomicrographs and drawings illustrating (1) gross and microscopic pathology of various benign and malignant tumors of the anal canal and (2) a number of ingested and inserted foreign bodies of the lower bowel The possible etiologic connection of benign anal lesions with cancer is shown and proper methods of removal of small and large rectal foreign bodies is illustrated

CLAUDE C TUCKER and C ALEXANDER HELLWIG St Francis Hospital, Wichita, Kan Normal and pathologic histology, clinical significance and operative treatment of anal ducts Exhibit of photographs and photomicrographs showing anal ducts in the human fetus and the new-born, in the adult and in different animals, photomicrographs of infected anal ducts, anal fistula and periproctitic abscess, photographs of operative treatment of anal ducts

Section on Radiology

Section exhibit committee S W DONALDSON chairman, Ann Arbor, Mich, C E HUFFORD, Toledo, and E P McNAMEE, Cleveland

In addition to the radiologic exhibits listed, a large amount of radiologic material will be found in exhibits in other parts of the hall

E V ALLEN and JOHN D CAMP, Mayo Foundation for Medical Education and Research, Rochester, Minn Arteriography Exhibit of roentgenograms made following injection of a radiopaque substances into the peripheral arteries of the living subject Arteriograms revealing normal vessels, congenital variations and appearances in thrombo-angitis obliterans, Raynaud's disease, scleroderma and arterial venous aneurysm will be shown together with a description of the technic of the method

VINCENT W ARCHER S D BLACKFORD and J E WISLER, University of Virginia Hospital, University, Va Radiologic pulmonary observations in tularemia Exhibit of reductions of chest films on a number of tularemia patients illustrating acute cases showing pneumonia, pleural effusion, marked bronchitis and nodular changes Follow-up examinations over a period

of months show residual pulmonary changes in many cases, a large percentage of the cases studied show definite pulmonary changes

FRANKLIN B BOGART, Pine Breese Tuberculosis Sanatorium, Chattanooga, Tenn Roentgenographic demonstration of early pulmonary tuberculosis showing necessity for repeated examinations in fulminating cases Exhibit of roentgenograms of a small group of cases illustrating (1) the importance of roentgen examination of the chest in early minimal involvement, (2) that a small group of tuberculous cases with a fulminating type of the disease are coming to the radiologist and clinician so early in the disease that it is not possible to demonstrate the lesions radiographically or clinically, and yet in a short period of time an extensive lesion is shown

SAMUEL BROWN, Jewish Hospital, Cincinnati Abdominal tumors Exhibit of roentgenograms illustrating (1) normal topographic relationship of the abdominal organs in the upright and prone anteroposterior and lateral positions, (2) anomalous positions of the abdominal organs of congenital and acquired origins (3) differential diagnosis of abdominal tumors by the roentgenologic method

JOHN D CAMP, Mayo Foundation for Medical Education and Research Rochester, Minn 1 Roentgenographic study of the osseous changes accompanying tumors of the spinal cord and associated soft tissues Exhibit of roentgenograms and transparencies of gross specimen photographs illustrating the various bone changes associated with soft tissue tumors within the spinal cord 2 Roentgenographic changes accompanying intracranial meningioma Exhibit of roentgenograms and transparencies of photographs of gross specimens depicting the various osseous changes in the skull occurring as a result of a contiguous meningioma

W EDWARD CHAMBERLAIN and BARTON R YOUNG Temple University Medical School, Philadelphia 1 Primary bone tumors Exhibit of transparencies demonstrating cases of primary bone tumors 2 Calcification (ossification) of normal laryngeal cartilages mistaken for foreign body Exhibit of transparencies and diagrams illustrating varied types of laryngeal calcifications which may be confused with foreign body

H KENNON DUNHAM Hamilton County Tuberculosis Sanatorium Cincinnati (a) Pulmonary emphysema with injection of iodized oil Exhibit showing that pulmonary emphysema as a complication of arrested far advanced pulmonary tuberculosis is of both medical and economic importance As a handicap it must be a factor in rehabilitation programs generally (b) Conditions simulating pulmonary tuberculosis Exhibit showing that nontuberculous cases are often sent in to a tuberculosis sanatorium and a knowledge of such conditions on the part of the general practitioner and the specialist is desirable

PAUL C HODGES, ALEXANDER BRUNSCHWIG and S PAUL PERRY, University of Chicago Chicago X-ray wavelength and skin tolerance Exhibit of charts, diagrams, pelts of experimental animals, and microscopic preparations Demonstration of the fact that the degree of reaction to irradiation depends solely on the intensity of the dose and is independent of wavelength

HOWARD B HUNT and J J KEEGAN, University of Nebraska School of Medicine, Omaha Radiographic and clinical correlation of meningeal tumors Exhibit of plain roentgenograms, encephalograms and photographs of a few specimens, together with histories and operative observations on several proved cases of meningeal tumors

JOHN S LEWIS JR and EDGAR C BAKER, Youngstown Hospital Association, Youngstown, Ohio Comparison of urinary tract in pregnancy and in the presence of pelvic tumors Exhibit of prints from films of intravenous or retrograde pyelograms in cases of pregnancy or pelvic tumors, demonstrating that both conditions show comparable dilatation of upper urinary tract, and that various causes given for dilatation in pregnancy are not all assignable to tumors

J M MARTIN and C L MARTIN, Baylor University Hospital, Dallas, Texas Radiation therapy in oral malignant growths Exhibit of photographs and drawings of actual cases of oral malignant growths illustrating in detail the macroscopic and microscopic appearance of these lesions at the time of treat-

ment, with later photographs showing the results of radiation treatment in each case

GEORGE E PFAHLER and JACOB H VASTINE, Philadelphia
Roentgen diagnosis of tumors of the bladder and their serial study under treatment by irradiation Exhibit of mounted roentgenograms ("pneumocystograms") showing the tumors the infiltrating or noninfiltrating character and the disappearance of some of them under roentgen treatment

Section on Miscellaneous Topics

Two subjects discussed by the Section on Miscellaneous Topics will be further illustrated in the Scientific Exhibit "Nutrition," by an exhibit put on by a special committee (see Special Exhibits) and "Forensic Medicine," by a symposium composed of a group of exhibits on this subject In addition there are a number of exhibits on varied topics dealing with different phases of medicine

Symposium on Legal Medicine The following three exhibits deal with different phases of medicolegal problems

R N HARGER, Department of Biochemistry and Toxicology Indiana University School of Medicine, Indianapolis Chemical methods for detection of drunkenness (a) Exhibit of automatic demonstration of the use of the "drunkometer, a device for detecting drunkenness by testing the subject's breath accompanied by charts showing that this method is a practical substitute for blood or spinal fluid analyses (b) Demonstration of a simple method of determining alcohol in body fluids and tissues (c) Simple test for diagnosing methyl alcohol poisoning (d) A method for analyzing an embalmed body to determine the existence of intoxication at the time of death

TIMOTHY LEARY, Medical Examiner Service Suffolk County, Boston The relation of cholesterol to atherosclerosis Exhibit of enlarged photomicrographs illustrating (a) human coronary sclerosis and (b) comparison of the lesions of human coronary and experimental rabbit atherosclerosis

MASSACHUSETTS MEDICO-LEGAL SOCIETY, Gilman Osgood, President, Boston Exhibit of photographs and documentary evidence dealing with various phases of medical jurisprudence

WILLIAM BIEMAN and E H FISHBERG, Beth Israel Hospital New York Some physiologic changes occurring during hyperpyrexia induced by physical means Exhibit of charts indicating changes in (a) chemistry of the blood, sweat and gastric contents (b) agglutinating and complement fixing factors of the blood serum (c) white cell count in the blood (d) the blood velocity (e) respiratory excursions (f) skin surface temperatures, (g) sedimentation rates (h) relationship between rectal and mouth temperatures respiratory rates and pulse rates

MAX CUTLER Michael Reese Hospital Chicago Exhibit of stereophotographs, wax models and molds charts, photographs and lantern slides illustrating the early diagnosis of cancer

W E KENDALL, P F BROWN, L H PRINCE and J W TURNER, in collaboration with MAX CUTLER, Chicago Veterans Administration Facility, Hines, Ill Early diagnosis and treatment of cancer of the skin and mouth Exhibit of photographs charts, colored lantern slides models and gross specimens showing results of necropsy in neglected cases of melanoma and carcinoma of the skin and mouth

GEORGE LEVENE Evans Memorial for Clinical Research and Preventive Medicine Massachusetts Memorial Hospitals, Boston Mechanical hearts Exhibit of a number of mechanical models, which reproduce the appearance of the heart as seen under the fluoroscope showing the normal heart sinus arrhythmia, extrasystoles, heart block auricular fibrillation thromboticosis, coronary disease aortic stenosis, aortic insufficiency and tricuspid insufficiency

CHARLES J SUTRO, Hospital for Joint Diseases New York Effect of chronic fluoride intoxication on teeth and bones Exhibit of enlarged photographs and roentgenograms showing the various changes in the teeth and bones of fluoride-fed rats, histologic sections showing changes in long bones and teeth Data and photographs will be presented of rats teeth to disprove the statement that fluoride action depends on parathyroid dysfunction, similar evidence to disprove the fact that low

calcium diet alone produces mottled enamel, roentgenograms of long bones of workers consuming cryolite (fluoride compound), showing advanced osteosclerosis

GRANT E WARD and J MASON HUNDLEY JR, Baltimore Combination treatment of cancer Exhibit of (1) illustrations of patients before and after operation, photomicrographs for diagnosis and to show histologic changes in tissue, (2) motion pictures showing technic of electrosurgery (3) demonstration of various types of electrosurgical apparatus, (4) wax models of cancer cases used especially for teaching purposes, (5) methods of radium therapy especially as applied to gynecology

GROUP EXHIBIT, Department of Anatomy and Associated Foundations Western Reserve University School of Medicine, Cleveland Growth and repair J C PIACAK The prenatal environment N W INGALLS Stages in embryonic development, normal and abnormal CARL C FRANCIS Growth in infancy and the preschool period T WINGATE TODD Maturity levels in grade and high school periods HARRY C ROSENBERGER B HOLLY BROADBENT and OSCAR TURNER Growth of the nasopharynx in the child Y A VENAR The role of vitamin D and amino-acids in skeletal growth W M KROGMAN Growth of the anthropoid B HOLLY BROADBENT Roentgenographic measurement of dentofacial development growth JOHN E L KEIES Features of orbital growth W B SEYMOUR JR The registration in the bones of constitutional handicaps ELMER F GOOEL Muscular tone as expressed in the foot print THEODORE A WILLIS The weight-bearing role of the leg muscles L DEWEY ANDERSON The measure of psychomotor, social and intellectual development in young children MARION N GIBBONS Osteochondritis and the growing child W KUENZEL The reactions of the alimentary tract to different food substances RUDOLPH S REICH The foot circulation Repair in shoulder dislocation C GLENN BARBER Repair as studied in amputation stumps THEODORE T ZUCK The therapeutics of growth encouragement in retarded children H C MOLOY and W E CALDWELL Anatomic variations in female pelvis JOHN P GARDINER The ischialramic diameter

Symposium on Amebiasis

Contributions to the Symposium on Amebiasis have been made by the Section on Gastro Enterology and Proctology, the Section on Pathology and Physiology, the Section on Pharmacology and Therapeutics, and the Section on Preventive and Industrial Medicine and Public Health

ARMY MEDICAL MUSEUM, United States Army Washington, D C Amebiasis Exhibit of photographs and photomicrographs showing Endamoeba histolytica compared with other ameba pictures showing histologic and pathologic phases of amebic dysentery compared with bacillary dysentery

LEWIS B BATES, LAWRENCE GETZ and WILLIAM M JAMES Medical Association of the Isthmian Canal Zone, Panama City Diagnosis and pathology of human amebiasis with special reference to infestation with Endamoeba histolytica Exhibit of (1) stool and culture preparations of the amebas of man, showing differentiation of species, (2) sections of tissue showing pathology of E histolytica, (3) gross pathology of infestation with E histolytica The appearance of the intestinal amebas in preparations from the stool and the microscopic and gross pathology of the lesions will be especially illustrated

FRANCIS BAYLESS, Institute of Pathology, Western Reserve University, Cleveland Methods of cultivating Endamoeba histolytica Exhibit and description of various types of mediums used in cultivation of Endamoeba histolytica with demonstration of living cultures from laboratory and clinical sources

MANFRED KRAEMER and MAURICE ASHER, Newark, N J The diagnosis of amebiasis by the proctosigmoidoscopic method Exhibit of charts and drawings showing method of making proctosigmoidoscopic examination, appearance of mucous membrane showing area from which smear is made, sigmoidoscopic appearance of bowel in diarrheas that might be confused with amebiasis Demonstration of warm stage examination of smear on a simple cheap rapidly constructed warm stage

C D LEAKE A C REED, H H ANDERSON and H G JOHNSTONE Pacific Institute for Tropical Medicine in the Hooper Foundation for Medical Research and Department of

Pharmacology, University of California Medical School, San Francisco The chemotherapy of amebiasis Exhibit showing the requirements of an ideal drug for treatment of amebiasis Laboratory criteria for evaluating relative merits of drugs proposed for use in amebiasis, toxic range of drug on single and repeated oral administration in various animals, rate of excretion, amebicidal concentration in vitro, effective range in natural balantidial infestation in guinea-pigs and in natural monkey amebiasis, controlled clinical trial Results of a survey of (a) ipecac and kurchi alkaloids, (b) halogenated oxyquinolines, (c) organic arsenicals and (d) miscellaneous antiseptics

THOMAS B. MAGATH, Mayo Clinic, Rochester, Minn. Amebiasis in kittens Exhibit of photographs and transparencies showing lesions in kittens suffering from amebiasis

ISAAC D. RAWLINGS, Chicago Board of Health Chicago Amebiasis The Chicago outbreak Exhibit of charts showing carriers in the general population and among food handlers, and the cases and carriers found in the Chicago outbreak, working model showing cross connection between a safe and a polluted water supply, motion picture showing living amebas

Symposium on Treatment of Burns

The Symposium on the Treatment of Burns is sponsored by the Section on Surgery, General and Abdominal, the Section on Practice of Medicine, and the Section on Pathology and Physiology In addition to the exhibits there will be a motion picture program run on a definite schedule in an area adjoining the exhibits

ROBERT HENRY AIDRICH, Boston Gentian violet in the treatment of burns Exhibit of photographs and charts of patients treated with gentian violet, charts showing bacteriology of burns, mortality before and after introduction of gentian violet, studies of fatal burns, showing increase in life expectancy with the use of gentian violet

SAMUEL GORDON BERKOW, Perth Amboy General Hospital Perth Amboy, N. J. Classification, healing time and significant blood chemistry of burns Exhibits of figures showing burns in adults and children with charts showing method of estimating (1) percentage of body surface involved (2) actual area involved, table computing healing time, based on area, depth of wound and age of patient (DuNouy and Carrel's equation), charts showing significant factors in blood chemistry in extensive burns, with special emphasis on those pointing to hypopnephrinemia

VILRAY P. BLAIR and J. B. BROWN, Department of Surgery, Washington University School of Medicine, St. Louis Exhibit of photographs and mounted drawings on the treatment of full thickness skin losses resulting from burns

D. M. GLOVER and A. F. SYDOW, St. Luke's and City Hospitals, Cleveland The repair of acquired skin defects Exhibit of diagrams and photographs illustrating the problems in restoring large areas of skin destroyed by burns the ideal method of skin transplantation, illustrations of the types of full thickness grafts in selected cases

ROBERT KAPSINOW and S. E. KAPSINOW, Lafayette La. Extensive superficial burns Exhibit of tables indicating use of hemoglobin readings and the value in prognosis table showing effect of forcing fluids on blood concentration changes, graphs showing relation between hemoglobin, water intake and urine output in immediately and delayed treated cases, and rate of absorption from site of burn

R. D. McCLURE and C. I. ALLEN, Henry Ford Hospital, Detroit The treatment of burns Past and present methods Exhibit of charts, photographs and motion pictures of past and present methods of treating burns, with a demonstration with material Special attention is given to the discovery and development of the tannic acid treatment by the late Dr. E. C. Davidson

GROVER C. PENBERTH, Children's Hospital of Michigan Detroit Davidson method of treating burns by tannic acid Exhibit of photographs and charts illustrating cases treated by means of tannic acid, a motion picture depicting method of treatment

STANLEY J. SEEGER, Milwaukee Children's Hospital Milwaukee Prevention and treatment of burns I Exhibit of

dioramas, charts and posters showing the importance of prevention, common causes of burns in children, possibilities of educational work by hospital organizations, motion pictures on prevention of burns suitable for use before lay groups 2 Exhibit of charts giving general outline of treatment, demonstration of method of applying tannic acid and the importance of pH value of tannic acid solutions, illustrated by photographs and photomicrographs

NORMAN TREVFS and GEORGE T. PACK, Memorial Hospital for Cancer and Allied Diseases, New York The development of cancer in burn scars Exhibit of transparent illustrations and charts showing experience at the Memorial Hospital for Cancer, clinical photographs, photomicrographs charts and illustrations showing methods of treatment and end results

Motion Pictures The following motion pictures will be shown on a definite schedule to be announced later

D. M. GLOVER, Cleveland "Tannic Acid Treatment of Burns" "Technique of the Thiersch or 'Split' Graft with Examples of the Results" "The Use of Full-Thickness Grafts—Free and Pedicled"

R. D. McCLURE, Detroit Tannic Acid Treatment of Burns

G. C. PENBERTH, Detroit "The Method of Treating Burns Used at the Children's Hospital of Michigan"

STANLEY J. SEEGER, Milwaukee The Prevention of Burns

Diseases of the Thyroid

A number of exhibits dealing with various phases of the thyroid problem have been grouped together

HERRMAN L. BIUNGART, J. E. F. RISFMAN, DAVID DAVIS and A. A. WEINSTEIN, with the surgical collaboration of DAVID D. BERLIN, Beth Israel Hospital and Harvard Medical School, Boston Treatment of angina pectoris and congestive failure by total ablation of the normal thyroid gland Exhibit of a study of a large number of patients with chronic heart disease treated by total thyroidectomy, charts indicating the rationale of procedure, selection of cases, clinical course, technique of operation postoperative management and complications, and mortality statistics motion picture of operation and of patients before and after operation data regarding changes in cardiac size and electrocardiogram blood cholesterol, calcium phosphorus, studies on early relief of pain, exercise test used for diagnosis of angina, and preoperative and postoperative photographs will be shown

JOSEPH FEISEN, Bronx Hospital New York Clinical types of thyroid dysfunction Exhibit of mounted stained specimens with individual folders containing photomicrographs and summarized clinical data individual graphs indicating iodine therapy, basal metabolic rate and postoperative course

HAROLD L. GOSS and HENRY F. HUNT, Geisinger Memorial Hospital Danville, Pa. Diseases of the thyroid gland Exhibit of photographs goitrous thyroids mounted with photomicrographs showing pathology of the condition and demonstrating various diseases affecting the thyroid gland i. e., carcinoma, active suppurative and nonsuppurative thyroiditis, adenomatous goiter with and without systemic symptoms and hyperthyroidism or exophthalmic goiter

G. ALLEN ROBINSON, New York Differential diagnosis of tumors of the neck Exhibit of photographs of benign, malignant primary and metastatic conditions including a classification of common and unusual tumors method of diagnosis and treatment of various neoplasms will be indicated

WILLARD O. THOMPSON, PHEBE K. THOMPSON, S. G. TAYLOR III and S. B. NADLER, Rush Medical College of the University of Chicago Presbyterian and Cook County Hospitals Chicago The pharmacology of the thyroid in man Exhibit of charts to correlate (1) the more important facts concerning iodine in relation to the treatment of goiter, (2) the comparative calorigenic effects, in myxedematous man, of most substances known to affect the basal metabolism

GROUP EXHIBIT Cleveland Clinic Foundation Cleveland Diseases of the thyroid R. H. NICHOLS, E. L. SHIFLETT and R. S. DINSMORE Roentgen studies of the thyroid D. ROY

EDUCATIONAL CLASSIFICATION

Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than of individuals and which are intended to show progress in the particular activities with which those institutions deal

AMERICAN ASSOCIATION OF HOSPITAL SOCIAL WORKERS, Chicago Some contributions of social work to the care of ill health Exhibit of material on social factors in disease as found by social workers in various hospitals and outpatient departments of the country

AMERICAN COMMITTEE FOR THE CONTROL OF RHEUMATISM Philadelphia Chronic arthritis Exhibit of moulages, old books and charts together with a motion picture on chronic arthritis

AMERICAN HEART ASSOCIATION New York Arteriosclerotic heart disease Exhibit will cover diagnosis, taking into consideration history, physical, roentgen and electrocardiographic observations, the relationship and differentiation between angina pectoris and coronary occlusion, prognosis and treatment

AMERICAN HOSPITAL ASSOCIATION Chicago Hospital construction, equipment and administration Exhibit of statistical graphs package libraries, transparencies and other material that is informative to the hospital field and members of medical staffs of hospitals

AMERICAN PHARMACEUTICAL ASSOCIATION, Baltimore The National Formulary Exhibit showing the use of the National Formulary in hospitals, with emphasis on the use of N F drugs, chemicals, preparations and prescriptions

AMERICAN SOCIAL HYGIENE ASSOCIATION, New York Treatment of syphilis Exhibit of cooperative clinic studies as follows Johns Hopkins University, JOSEPH EARLE MOORE, University of Pennsylvania, JOHN H STOKES Mayo Clinic PAUL A O'LEARY, Western Reserve University HAROLD N COLE, University of Michigan UDO J WILE in cooperation with TALIAFERRO CLARK, United States Public Health Service

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Denver Registration of laboratory technicians Exhibit of charts showing distribution of laboratory technicians photographs and placards illustrating the work of the board of registry and the American Society of Clinical Pathologists

CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM Pneumothorax Clinic, Chicago Collapse therapy in pulmonary tuberculosis Exhibit of roentgenograms showing indications for collapse, technic, complications and results Correlated pathologic exhibit showing the relationship between roentgenograms and the actual pathologic conditions, as demonstrated by lung specimens

CLEVELAND RADIOLOGICAL SOCIETY Cleveland History and progress of radiology Exhibit of prints and actual material showing early work in roentgenology a demonstration of the various roentgen examinations that can be made in the investigation of a particular patient for a particular pathologic condition

HEART COUNCIL OF GREATER CINCINNATI Cincinnati Studies of cardiovascular disease Exhibit of charts, graphs, electrocardiographic tracings, radiograms and specimens resulting from research studies conducted by the staff of the Heart Council of Greater Cincinnati

MUSEUM OF HISTORICAL AND CULTURAL MEDICINE CLEVELAND MEDICAL LIBRARY ASSOCIATION Cleveland Exhibit of a collection of monaural stethoscopes

NATIONAL BOARD OF MEDICAL EXAMINERS Philadelphia Exhibit of charts describing the work and progress of the National Board of Medical Examiners

NATIONAL TUBERCULOSIS ASSOCIATION, New York Pathologic sequence of pulmonary tuberculosis Exhibit of roentgenograms illustrating successive steps in the development of pulmonary tuberculosis from primary complex to chronic widespread pulmonary involvement Motion picture of thoracoplasty operation and results

UNITED STATES PHARMACOPEIAL CONVENTION, Washington D C The United States Pharmacopeia Exhibit showing the use of the Pharmacopeia in hospitals with emphasis on the use of U S P drugs, chemicals, preparations and prescriptions

VETERANS ADMINISTRATION, Medical and Hospital Service Washington, D C Clinical and postmortem observations in a group of veterans with cardiovascular disease Exhibit of graphs and statistical tables showing postmortem observations in veterans with heart disease heart disabilities will be classified according to etiologic factors, anatomic types and abnormal physiology, the postmortem data will include information on anatomic types of cardiovascular disease, the coexisting general diseases, and data on age and race

AMERICAN MEDICAL ASSOCIATION

The exhibits from the headquarters group of the American Medical Association will be found in various parts of the hall

BUREAU OF HEALTH AND PUBLIC INSTRUCTION Professional participation in public health effort Exhibit of maps indicating state and county societies showing noteworthy activities in health education and medical participation in public health work by state and county medical societies

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS Exhibit of charts showing the leading facts of importance regarding medical education, licensure, internships and residencies, status of listing of specialists, latest available data on hospital occupancy and other hospital statistics

COUNCIL ON PHARMACY AND CHEMISTRY, CHEMICAL LABORATORY BUREAU OF INVESTIGATION AND COMMITTEE ON FOODS These will present collective exhibits to illustrate the weaknesses of the present National Food and Drugs Act, and to emphasize the urgent need for more comprehensive national food and drug legislation in the public interest

COUNCIL ON PHYSICAL THERAPY Exhibit of motion pictures, charts, instruments and simple equipment designed to substantiate the physiologic effects of physical therapy procedures employed in the practice of physical therapy, including such therapeutic procedures as heat massage, therapeutic exercise and hydrotherapy

AWARDS

There will be two classes of awards, consisting each of (a) a gold medal, (b) a silver medal, (c) a bronze medal and (d) three certificates of merit

NOTE—The special (subsidized) exhibits (Encephalitis Exhibit Nutrition Exhibit and demonstrations in Pathology) and the exhibits of the headquarters of the American Medical Association are not open to awards

CLASS I

Awards in class I are made for exhibits of individual investigations which are judged on basis of originality and excellence of presentation

CLASS II

Awards in class II are made for exhibits which do not exemplify purely experimental studies which are judged on the basis of excellence of correlating facts and excellence of presentation

Medals are awarded only to individuals A special certificate of merit will be awarded to the best educational exhibit in the Educational Classification (this includes exhibits by national organizations, and the like) The decisions of the Committee on Awards will be final and will not be subject to review

The Committee on Awards will be composed of five persons It will make its decisions on Wednesday The names of the Committee on Awards will not be available until after the decisions have been published

THE BILLINGS MEDAL

The late Dr Frank Billings, during his lifetime, as one of the leaders of the American Medical Association was responsible more than any other individual for stimulating the scientific exhibit idea and encouraging the progress of this work both in and out of the meetings and assemblies of the Association

The exhibit was started in 1899 at the Columbus session through the activities of the Indiana State Medical Association. A pathologic exhibit was the feature of the exhibit and was continued as such for the next several years under the supervision of the then newly formed Section on Pathology and Bacteriology with the active cooperation of Dr Frank B Wynne, as chairman of the committee. In 1903, under the presidency of Frank Billings the exhibit was broadened in scope to include all phases of scientific medicine, and hence was named Scientific Exhibit

Awards of medals and certificates were first made to the best exhibits shown in 1908. When this proposition was presented to the House of Delegates when it met the previous year, it was the influence of Frank Billings that prevented the matter from dying without action

A crucial period of the Scientific Exhibit came in 1920. For several years the direction of the exhibit had been passed around from one person to another, with a lagging interest and enthusiasm. The Board of Trustees took an active interest in the problem and authorized a committee to prepare "plans for increasing the attractiveness of the Scientific Exhibit". Dr Frank Billings and Dr D Chester Brown were made members of this committee. At this time there was almost no appropriation for the Scientific Exhibit and requests for additional funds were at first denied. Dr Billings continued his interest in the Scientific Exhibit almost up to the time of his death.

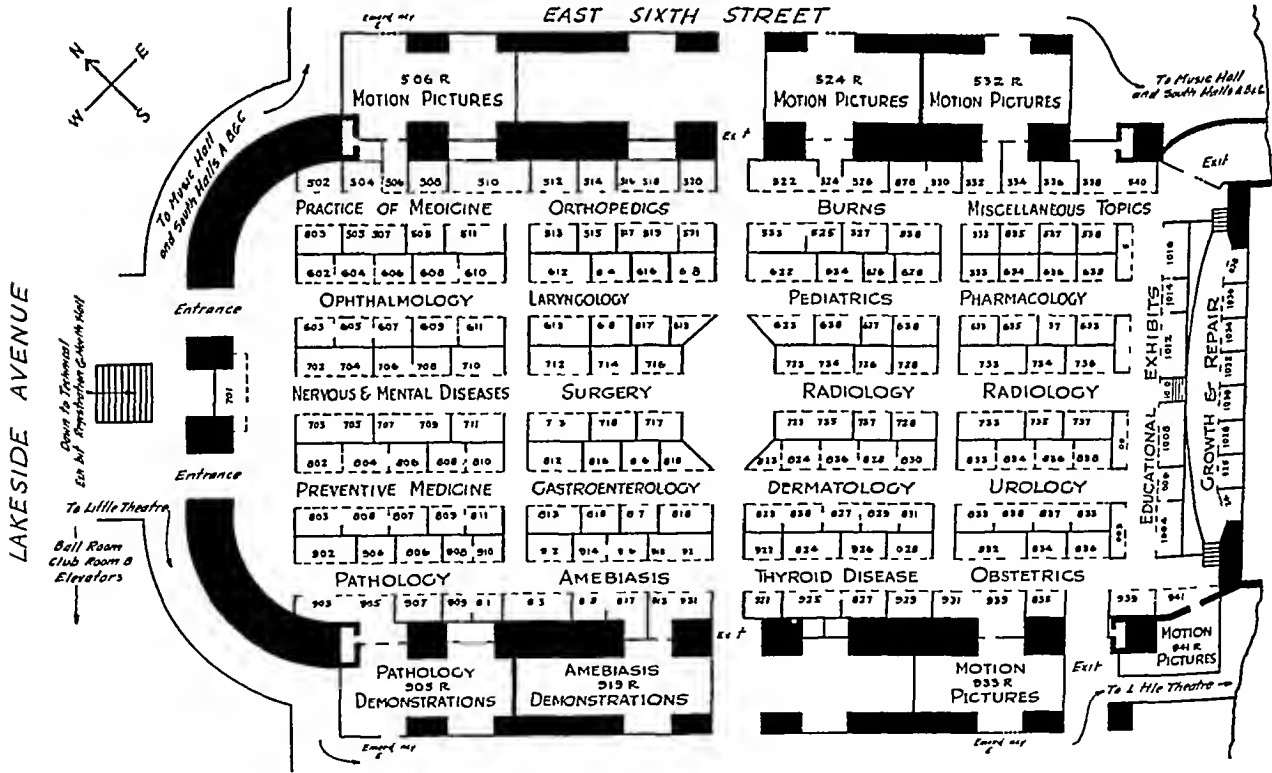

There have been numerous men who have made valuable contributions to the Scientific Exhibit in the past thirty-five years. But Frank Billings, not only by his standing in the medical world but also by his ceaseless labor for the betterment of scientific medicine, contributed so much to the development of the Scientific Exhibit that the use of his picture on the medal which is awarded annually in the Scientific Exhibit, is a compliment to the standing of the Scientific Exhibit and an expression of lasting appreciation for his inspirational leadership.

FLOOR PLAN OF SCIENTIFIC EXHIBIT

The Scientific Exhibit located on the Arena Floor of the Cleveland Public Auditorium will be the largest in the history of the Association. The quarters are adequate, however to accommodate both the exhibition and the visitors and provision has been made for seating arrangements at frequent intervals throughout the hall.

Further illustrated in the Scientific Exhibit thus making it possible for the physician who has heard the paper read to study the subject further at his leisure and to ask questions of the author.

Motion picture programs will be shown on definite schedules in areas provided for the purpose, directly adjacent to the

Sixteen sections of the Scientific Assembly are taking an active part, details of which have been given in the preceding pages. Special section exhibit committees have been engaged in selecting the best material possible in the various specialties. A large number of the papers read before the sections will be

section exhibits, by the Section on Practice of Medicine and the Section on Obstetrics Gynecology and Abdominal Surgery. Additional motion pictures will be shown on burns in an area adjacent to the symposium on burns, while a large number of motion pictures will be shown in individual booths.

THE TECHNICAL EXPOSITION

Difficult business conditions during the past few years have served as a challenge to inventive genius and research in practically every line of industry.

How this challenge has been courageously met and accepted by those firms which cater to physicians' needs will be concretely demonstrated in the exhibits of the Technical Exposition of the Cleveland Session. The occurrence and recurrence of the word "new" throughout the exhibit descriptions on the following pages is indeed significant. It is not an idle repetition, but an indication that scientific research has gone on despite adverse economic conditions, and that medical firms have increased their usefulness to the profession in manifold ways by developing new products or services.

It is this ability to impart new ideas, furnish new suggestions or demonstrate new methods that makes the Technical Exposition of pronounced educational value to the visiting physician. In a short amount of time, he can acquire a first-hand acquaintance with the latest developments of firms located in widely separated parts of the country.

But, while new instruments and apparatus, new books, new dietetic products, new medicinal prepara-

tions will be found on all sides, it should be remembered that exhibitors are also present to impart useful information regarding the standard and longer used articles. The Exposition as a whole represents practically all of the important products used in the practice of medicine. With almost 175 firms participating, and with all exhibits conveniently arranged on the lower level of the Auditorium, every minute of time spent in the Technical Exposition can be made stimulating and profitable. The Registration Bureau, the Postoffice, Lounge, Ticket Validation counter and several Section Meeting Halls will be found on this same level. Attendants with specialized knowledge in their respective fields will be in charge of the booths. Courteous treatment without undue urging to buy may be expected.

The exhibits will be open from 8:30 a. m. to 6:00 p. m. each day, except on Friday, when the closing hour will be at noon. The descriptions of the individual exhibits that follow are arranged alphabetically by firm names to facilitate easy reference.

WILL C BRAUN,
Superintendent of Exhibits

ABBOTT LABORATORIES

Halliver Oil Products

Since nutritional factors as never before, are engaging the attention of the forward-looking physician, Halliver Oil Products will occupy a prominent place in the Abbott exhibit. Booth 66. Chemical, sales and clinical research men will be in attendance and will be glad to discuss the numerous Council Accepted Abbott products with you. Pollen Extracts and charts of the pollen incidence in your own locality will also be featured. Call and place an order for your chart, which will be furnished free of charge.

ADLANCO X RAY CORPORATION

Ultra Short Wave Therapy

Several types of Ultra-Short Wave and Short Wave apparatus will be exhibited in Booth 186 by the Adlanco X-Ray Corporation, pioneers in this new therapy. Trained men will be on hand to explain the apparatus which is new to many members of the profession. The mystery of short electrical waves from 30 to 10 meters, and especially of ultra-short waves from 10 to 3 meters, has introduced a new and important factor in physio-therapy, and the results obtained will be discussed at this exhibit.

W D ALLISON COMPANY

New Pediatric Table

The new Allison-Ramsay Pediatric Table will be shown for the first time at an A. M. A. meeting by the W. D. Allison Company, manufacturers of physicians' wood furniture for the past fifty years. Many other late models of doctors' treatment room furniture, outstanding in quality and reasonable in price, will also be exhibited in Booth 94. The salesmen in charge will be glad to explain in detail the features of this fine furniture.

A S ALOE COMPANY

Cold Ray Quartz Ultraviolet Lamp

A striking feature of the Aloe exhibit, Booth 33, will be the new Cold Ray Quartz

Ultraviolet Lamp which has recently been accepted by the Council on Physical Therapy. This unit has been carefully tested in various clinics and has satisfactorily met all requirements. Another feature of this exhibit will be Stille Rustless Instruments at a special discount. A full line of surgical instruments, hospital and office furniture and physical therapy apparatus will be shown also.

AMERICAN OPTICAL COMPANY

New Improved May Ophthalmoscope

Important among the ophthalmic diagnostic instruments the American Optical Company will show in Booths 128 and 129 will be the new improved May Ophthalmoscope. This instrument presents a totally reflecting prism which bends the light instead of reflecting it, eliminating shadows and reducing corneal reflexes to a minimum. The convenient 'bryonet method' of attachment and a uniform round light controlled by a rheostat. Other new and important developments in eye, ear, nose and throat diagnostic instruments will be shown.

D APPLETON CENTURY COMPANY

Entire Line to Be Shown

Included in their entire standard line of medical works to be displayed by D. Appleton Century Co. in Booth 45, will be the 6 published volumes of their 'Practitioners Library of Medicine and Surgery.' These will give a clear idea of the scope of the Library, which is being supervised editorially by Dr. George Blumer. New editions will be shown of Holt and Howland's 'Diseases of Infancy and Childhood' (revised by Holt and McIntosh), Barton and Yates' 'Symptom Diagnosis,' and Zinsser and Bayne-Jones' 'Textbook of Bacteriology.' A new work to be shown is Wolf's 'Textbook of Physical Therapy.'

ARMOUR AND COMPANY

Sources of Gland Preparations

Armour and Company's exhibit, Booth 26 will be more than just a display of products. It will depict the sources of various pharmaceuticals, surgical ligatures, etc.—all in meat animals. Along with a vial of pituitary liquid will be the glands from

which the substance is extracted. Thyroid glands from the throats of cattle, sheep and hogs will illustrate the source of many thyroid preparations. Dozens of other exhibits of this nature will be shown, and competent men will be in attendance.

AZNOE'S

Medical Personnel Bureau

Aznoe's, the first medical personnel bureau (established in 1896) will be represented in Booth 153 by the director, Mrs. Bates. She will be pleased to explain to anyone seeking assistance how Aznoe's can be of service, and to those persons who are looking for a change, a location or a salaried appointment she will be glad to tell how Aznoe's nation-wide service can assist them.

BATTLE CREEK FOOD COMPANY

To Show Savita

Be sure to stop at Booth 27 for a treat! The Battle Creek Food Company will serve sandwiches spread with Savita, a yeast extract resembling meat but having the properties of pasteurized brewers' yeast.

W A BAUM COMPANY, INC.

Train Model of Duralumin

W. A. Baum Company will exhibit a large model of the Union Pacific's new high-speed train at Booth 28, emphasizing the utility of Duralumin. Both the train and the new Koppak Model Lifetime Baumanometer are built of Duralumin, the copper-aluminum alloy possessing the strength of steel with only one-third the weight.

BAUER & BLACK

Research Results to Be Shown

The results of a basic research program instituted by Bauer & Black more than five

years ago will be shown in Booths 122 and 123 where adhesive plaster, sutures absorbent cotton, gauze bandages, elastic stockings, Handi-Cast plaster of paris bandages, suspensories, Handi-Tape dressings and athletic supporters will demonstrate improvements will be exhibited. Bauer & Black's research has not been confined to the laboratory, but has gone into the field as well. This has resulted in a suspensory guide which will be available to physicians at the exhibit.

BAUSCH & LOMB OPTICAL COMPANY

Microscope for Laboratory Work

One of the instruments which will be shown by the Bausch & Lomb Optical Co. in Booth 6 is the model HA Physicians' and Medical Students Microscope. You are invited to inspect this instrument which is superior for laboratory use because of its weight, balance and stability. Note that its newly designed mechanical stage permits the systematic examination of the entire surface of a 75mm x 50mm slide.

BECTON, DICKINSON & CO

New Automatic Hypodermic

Becton Dickinson & Co. will display the new B-D Busher Automatic Injector, a self-injecting hypodermic unit which relieves nervous uncertainty, also the new B-D Blood Transfusion Outfit which simplifies transfusion to a one-man operation, and the new style Utility Manometer for hospital and office use. Other B-D products, many of them improved will be displayed and information given concerning them by attendants in Booths 37, 38, 39 and 40.

BILHUBER KNOLL CORPORATION

Disauid the New Morphine Derivative

In Booth 24 the Bilhuber-Knoll Corporation will display Disauid the morphine derivative, and offer evidence of its advantages as an analgesic in painful conditions and as a cough sedative. Among other products shown will be Theocaine, the diuretic and myocardial stimulant indicated in congestive heart failure and angina pectoris. Metrazol, the circulatory and respiratory restorative and also Bromural and Euresol. Well informed representatives will be glad to give interested physicians detailed information on these products.

BOVRIL OF AMERICA

A Famous Rich Beef Drink

Bovril a highly concentrated beef extract scientifically combined with highly concentrated extract of fresh brewers' yeast has been prescribed by eminent British and continental physicians for nearly half a century. Bovril has been accepted by the Committee on Foods of the A. M. A., and its vitamin B potency is recognized by the Privy Council for Medical Research in England. It will be demonstrated in Booth 112 where physicians may obtain descriptive literature.

P. BLAKISTON'S SON & COMPANY, INC.

To Show Series

"The Recent Advances in Medicine" Series present in concise, well written volumes the newer things in the various fields of medicine. This series, which has been augmented by several new volumes and new editions, will be shown with other desirable books in Booth 78, occupied by P. Blakiston's Son & Co., Inc.

BUCK X RAY COMPANY

Developments in X Ray Supplies

If you are interested in x-ray work, either from the standpoint of improving your present equipment or of purchasing new, you will find something of value in Booth 195. The Buck Company will show some innovations in the manufacture of developing tanks and illuminators, and will also have an attractive display of other items necessary to complete the modern x-ray dark-room.

BURDICK CORPORATION

Physical Therapy and Electrosurgery Equipment

In Booth 68 The Burdick Corporation will exhibit a complete line of modern physical therapy and electrosurgery equipment. In the physical therapy field it will feature the Council Accepted D-2 Diathermy, Anniversary model Ultra-violet Lamp and Dual Aonlie. For electrosurgery the products of greatest interest will be the SU-2 blended current Electro-surgical unit and the new D-3 machine for electrocoagulation.

CAMERON SURGICAL SPECIALTY COMPANY

New Electrically Lighted Instruments

Cameron Surgical Specialty Company will display a complete line of their electrically lighted Surgimold Instruments, for diagnostic and operative use. Their new colposcope instrument, the Tele-Vaginalite will be shown in three sizes with 10x Telescope. They will also show the Cameron Cauleodine line original portable Radio Knife with the new handle current control which is one of the noteworthy innovations of electro-surgery offering complete assurance of safety when cutting in a wet field and is particularly adapted to the prostate resection operation. Booth 105.

CARNATION COMPANY

To Demonstrate Solid Curd Milk

How the curds of various forms of milk are acted upon by an artificial gastric juice will be shown in Booths 154 and 155 by the Carnation Company, producers of Carnation Evaporated Milk. The effect of homogenization on the size of the fat globules in this milk will also be demonstrated. Carnation officials state that an important product improvement of special interest to pediatricians will be given publicly at this time.

S. H. CAMP & COMPANY

New Designs for Supports

Complete information on the latest developments of Camp Anatomical Supports will

be given at Booth 65 by representatives of S. H. Camp & Company. Latest designs for prenatal and postoperative visceroploids, and hernia, together with sacro-iliac, dorso-lumbar, and lumbosacral supports will be of interest to attending physicians.

WILMOT CASTLE COMPANY

Three New Sterilizers

The modern trend in sterilizer design will be shown by three new sterilizing outfits which the Wilmot Castle Company will display in Booth 126. One is a new popular priced instrument sterilizer and cabinet in which the instrument sterilizer is recessed and operated by a foot lift. This new model will be priced even lower than the older type cabinet with sterilizer at the side. Another model is a new specialists' outfit, and the third is a complete small pressure equipment for clinics and small hospitals. You are invited to examine them.

CHAMBERLIN METAL WEATHER STRIP CO.

Weather Strips and Screens

Visit Booth 183 and examine the interesting display of fuel saving equipment made by the Chamberlin Metal Weather Strip Co. If you will leave your name and address for a heat loss survey of your home or building, it will be given to you and carefully explained when computed—with the firm's compliments and no obligation on your part.

CHAPPEL BROS. INC.

Will Exhibit Liver Extracts

Complete maintenance charts of pernicious anemia patients carried through for over two years with Chappel's Liver Extracts will be shown in Booth 193 by the Chappel Bros. Laboratories. Chappel's Oral Liver Extract is a palatable highly purified liquid of reliable potency which is under constant hospital control. The injectable form is sufficiently refined to permit subcutaneous use without hazard. Each batch is tested for potency before being released for sale. Competent detail men will be in attendance.

CIBA COMPANY INC.

An Effective Amebiasis Vioform

The recent publicity on amebiasis has caused many physicians to seek new agents to combat this disease. Vioform, Ciba, through the efforts of Lenke et al., has proved to be one of the most effective amebicides. A special display of Vioform is included among the scientific exhibitions in Booth 85 the Ciba Company, Inc., will feature not only Vioform but also Digifoline Dial, Nupercaine, Lipodoline and Aloquinol.

CHURCH & DWIGHT COMPANY INC.

Sodium Bicarbonate

The exhibit of Church & Dwight Company, Inc., in Booth 150 will emphasize the pu

CLEVELAND PUBLIC AUDITORIUM

(Diagrammatic Cross Section)

Showing Location of Section Meetings, Scientific Exhibit, Technical Exhibit

richly, availability, and low cost of Arm and Hammer and Cow Brand Baking Sodas. These products which are identical, are Sodium Bicarbonate U S P. Physicians will be interested in them as their cost is extremely low and they are available in nearly every household. The booth will be of early American design simple and dignified and symbolizing the age when this firm began the manufacture of these brands of Sodium Bicarbonate in 1846.

HAROLD H CLAPP INC

Strained Baby Foods

The new Enamel Purity Pack of Clapp's Strained Baby Foods was first announced to the medical profession at the Milwaukee meeting last year. That the profession approved has been made evident during the ensuing months. This package, together with the original glass line, will be exhibited by Clapp in Booth 110.

WARREN E COLLINS INC

Combination Respirator Incubator

The latest models of the Drinker Infant Respirator, Burgess Collins Oxygen Tent and Benedict-Roth Metabolism apparatus will be displayed by Warren E Collins, Inc., in Booth 5. The combination respirator-incubator has new improvements of interest. The oxygen tent which operates on an entirely new principle, cuts oxygen therapy costs in half. The new Benedict-Roth has many new features which add to the patient's comfort and the ease of operation. See these demonstrated.

DAVIS & GECK INC

Sutures for Special Purposes

Their complete line of sterile surgical sutures will be shown by Davis & Geck in Booth 131. On display, also, will be several new items, including special purpose sutures with atraumatic needles adapted for tonsil, thyroid, obstetrical, circumcision plastic and eye work. They will show films from their Library of Surgical Motion Pictures to which many new subjects have been added since last year.

DAVIES, ROSE & COMPANY LTD

Pharmaceutical Preparations

Physicians prescribing preparations made by Davies Rose & Co Ltd, are assured of uniformity and dependability maintained by laboratory determination and supported by clinical experience. A visit to this firm's exhibit in Booth 46 should prove of interest to visiting physicians.

R B DAVIS COMPANY

Will Serve Cocomalt

Visit Booth 70 and be served with Cocomalt, a popular food drink supplying rich calcium, phosphorus and vitamin D content in a particularly delicious form. Miss Elsie Stark, director of the home economics department of the R B Davis Company, will be in charge of the Cocomalt booth. New Food Value Charts (calcium, phosphorus, vitamin D and calorie value) will be available for those who desire them.

F A DAVIS COMPANY

"The Cyclopedra of Medicine"

Seven hundred carefully selected physicians and surgeons from all civilized countries have produced under George Morris Pier-

son "The Cyclopedra of Medicine" in 12 volumes. Ten of these are now ready and may be examined at the F A Davis Company's exhibit. This notable work covers every phase of internal medicine, major and minor surgery and all the specialties, and a supplementary volume issued yearly keeps the Cyclopedra always up-to-date. Other standard works on various branches of modern medicine and surgery will also be displayed. Booth 73.

DE PUY MANUFACTURING COMPANY

Improvements in Fracture Appliances

Some of the most advanced improvements in fracture appliances will be shown by the De Puy Manufacturing Company in Booth 58. One feature is the new Granberry Hyperextension Frame which will fit on any hospital bed and which permits the surgeon to get direct hyperextension immediately beneath the point of fracture of any vertebra between the shoulder and the pelvis. Also on display will be the Forrester Head Sling, the Campbell Acroplastic Splint, the Granberry Arm Reduction Frame, the Lester Rocking Leg Splint, the De Puy Portable Fracture Table, the Neuhirner Adjustable Forearm Splint, Key's Kirschner Bow and the Well Leg Splint.

DETROIT COVER COMPANY

New Inhalant Device

There is considerable discussion of Arizona, the new inhalant device for use as an adjunct to the treatment of disorders of the nasal and respiratory tracts. This instrument, which recently was accepted by the Council on Physical Therapy, will be the attraction in the exhibit of the Detroit Cover Company, Booth 146. Arizona provides a direct means of reaching the nasal passages and lungs with medicated vapor or dry heat. A mask fits tightly over the nose and mouth and is connected with a heat and vapor chamber. All inhaled air is drawn through a heating element.

DO/MORE CHAIR COMPANY

Correct Posture Chairs

seated employees and executives in offices and factories.

DE VILBISS COMPANY

Nasal Guard for Atomizer

A complete line of atomizers and vaporizers for home and professional use will be displayed in Booth 43 by The DeVilbiss Company. A prominent feature of the exhibit will be the recently developed DeVilbiss Nasal Guard which prevents any excess pressure in the nasal passages during prescribed self-treatment. All visitors are cordially invited to visit the DeVilbiss display.

DUKE LABORATORIES INC

Will Distribute Nivea Creme

Physicians' wives golfers bothers motorists, self-shavers and oil those in need of an emollient cream for skin comfort protection and cleansing will find tubes of the familiar Nivea Creme awaiting them in Booth 7. The Duke Laboratories Inc will also have on display the new liquid cream Nivea Skin Oil.

DU PONT FILM MANUFACTURING CORPORATION

To Feature Radiographs

The DuPont Film Manufacturing Corporation invites you to visit Booth 206 and inspect the display of radiographs representative of its X-ray film which is particularly suitable for summer use.

EARNSHAW KNITTING COMPANY

New Vanta Developments

Nurse Hubbard will be at Booth 18 to show you the Vanta Baby Garments, manufactured by the Earnshaw Knitting Company, to conform to the ideas of doctors, nurses, and hospitals. Every effort is made to have the garments absolutely safe for baby and convenient for the mother. Allayette sizes are sterilized in regular hospital apparatus. This company originated dressing babies without pins or buttons. 'Self-Help' garments, sun suits and many of the things that have aided the physician to bring health and comfort to the baby.

EASTMAN KODAK COMPANY

Infra-Red Clinical Photography

On account of the diagnostic possibilities of infra-red clinical photography, you will be interested in the display of the Eastman Clinical Camera. This is ideally suited to this purpose. Besides an exhibit of radiographs made on Eastman Ultra-Speed Safety X-ray film, there will be distributed to members of the profession authoritative texts on the subjects of photography and radiography. Medical Division representatives of the Eastman Kodak Company will gladly answer questions regarding your radiographic or photographic problems and demonstrate any of the equipment on display in Booths 198 and 199.

ELECTRO SURGICAL INSTRUMENT COMPANY

New Electrically Lighted Instruments

You are invited to see the demonstration of new electrically lighted surgical instruments by the Electro Surgical Instrument Company in Booth 194. A complete line of cautery transformers, electrodes and accessories will also be on display. Of great interest to the bronchoscopist will be the bronchoscope instruments constructed of an entirely new non-corrosive metal which requires no plating and always retains its luster and cannot be bent or crushed by the patient's teeth while in use.

J H EMERSON

Will Exhibit New Products

A syringe blood transfusion apparatus, an automatic temperature control for intravenous injection apparatus for recording photographically the sedimentation rate of blood (up to ten determinations simultaneously) and an inexpensive design of negative pressure chamber for treating peripheral vascular diseases will be shown by J H Emerson in Booth 149. Latest designs of his familiar products will also be exhibited: the Barcroft-Warburg and other research apparatus, simple portable oxygen tents and adult and infant respirators.

ENOCHS MANUFACTURING COMPANY
To Exhibit New Modern Suite

You are invited to inspect the new Modern suite of physicians' office furniture displayed by the Enoch Manufacturing Co in Booth 111. It is designed for this "stream-lined" age, yet there is nothing freakish or bizarre about it.

**H G FISCHER & COMPANY**

Electrotherapeutic Demonstrations

Three interesting pieces of apparatus in the exhibit of H G Fischer & Co will appeal to physicians interested in electrotherapeutic equipment. These are the new Fischer Short Wave High Frequency Apparatus, the new Fischer 60-88 Universal Shock-proof Diagnostic X-ray, and their model H Diathermy and Electrocoagulation Unit recently accepted by the Council on Physical Therapy. See these demonstrated in Booth 5.

FORM PUBLISHING COMPANY

Collins Diet Calculator

The Form Publishing Company will have available in Booth 158 the Collins Diet Calculator, which has been accepted by a large majority of practicing physicians in the U S as the most important and practical aid in writing any calorie diet in medicine. It contains 1800 menus on one chart and can be used in diabetes, cardiovascular disease, nephrosis and epilepsy. They will also show the new Collins Oesophagus Diet Chart which contains 100 reducing diets on one chart.

E FOUGERA & COMPANY

Will Display Lipiodol

A cordial invitation is extended to all physicians to visit the display of this firm which, for 85 years has been supplying American physicians with outstanding French Swiss and English pharmaceuticals. The display will feature Lipiodol, an iodized oil designed for lipodiagnostics and as a substitute for inorganic iodides. Pictures will demonstrate its application to the central nervous system, respiratory tract, utero-tubal exploration and the accessory nasal sinuses and detailed information will be given concerning Lipiodol as an opaque contrast medium for radiographic diagnosis. Booth 109.

GEBAUER CHEMICAL COMPANY

Ethyl Chloride C P

Gebauer's Ethyl Chloride C P will be exhibited in Booth 147. Physicians are invited to inspect the metal tube in which it is supplied, and which is equipped for either spray or drop administration.

**GENERAL ELECTRIC COMPANY**

Intelligent Use of Lighting

See the latest developments in lamps and lighting, and G E's now famous Science of Seeing in the General Electric Company's exhibit Booth 118. See how readily an intelligent use of lighting can relieve us human seeing machines of eye strain and of the drain we impose on our energy when we struggle to perform severe visual tasks under improper seeing conditions. Get on more intimate terms with the Indoor Sun ultra-violet from G E Mazda sunlight lamps and help yourself to vitamin D, the sunshine vitamin.

GENERAL ELECTRIC X RAY CORPORATION

Shock Proof X Ray Units

The Model "T" Portable Shock Proof X-Ray Unit will be one of several new designs to be shown by the General Electric X-Ray Corporation, and radiographs showing the quality of work that it is possible to do with this small, compact unit will prove a real surprise. The G E Inductotherm, the most simplified and efficient method ever developed for creating heat within the tissue and for producing therapeutic fever will also be featured. Apparatus for electrocardiography, electrosurgery, and electrocoagulation ultra-violet quartz lamps, infra-red lamps, etc., will offer many practical suggestions to physicians for valuable additions to their office equipment. Booths 13, 14, 15 and 16.

GENERAL MILLS INC

All About Bread

Bread is nutritional properties and its many and varied uses in the diet will be the feature of the General Mills display in Booth 21. A "moving wheel" chart graphically illustrating bread and baked wheat foods as the hub of the balance wheel of the diet will show bread in combination with various other foods. It will explain how these combinations of food provide the nutritive elements such as proteins, minerals, vitamins and carbohydrates that are necessary in a well balanced diet. A book containing the latest correct information on baked wheat foods will be given to physicians visiting the booth.

HANOVIA CHEMICAL & MANUFACTURING CO

For Milk Irradiation

A feature of the Hanovia exhibit Booth 127 will be the Hanovia National Irradiator for vitamin D activation of milk, embodying an automatic ultra-violet intensity control and recorder.

Of particular interest also will be the new quartz-mercury Super Alpine Sun Lamp for general body irradiation; the quartz-mercury Super Self-contained Kromayer Lamp for local application and the Physicians' and Specialists' Models Solux Radiant Heat Lamps for the application of infra-red rays. Special hospital model lamps will also be on display. Trained representatives will be in attendance at this interesting exhibit.

**CHR HANSEN'S LABORATORY INC**

Junket Powder and Tablets

The Junket Folks will be on hand to welcome you to Booth 47 where a dietitian will show how easily milk may be made into delicious and attractive desserts, milk drinks and ice cream. Recent research shows that milk with Junket digests faster than milk alone and this explains why many people who cannot drink milk can eat Junket. Junket Tablets, not sweetened or flavored, are useful for non-sugar and special diets. Visit the Junket booth for samples and further information.

**HEALTH PRODUCTS CORPORATION**

Cod Liver Oil Concentrate Tablets

In Booth 116 the makers of White's Cod Liver Oil Concentrate Tablets will show the manufacturing processes from the fish to the palatable little tablets. They will explain the year-round benefits of these tablets which are as effective and easy to take in mid-summer as in winter and are always constant in vitamin content and accurate in dosage.

HAWAIIAN PINEAPPLE COMPANY

Pineapple Juice to Be Served

A product that will appeal to all who are interested in pure fruit juices as an important part of the daily diet is Dole Pineapple Juice which the Hawaiian Pineapple Company will exhibit in Booth 131.

It has many known nutritional properties, and contains no muck or fuss in serving. Its value in the diet of children and as a source of vitamins A, B and C, of mineral salts, food acids, and natural sugars, will be shown. Call at this exhibit for a drink of natural golden juice of fresh, ripe pineapples. You will find it refreshing and unusual.

H J HEINZ COMPANY

New Facts About Baby Feeding

In addition to displaying an interesting line of products, H J Heinz Company will have a member of its research department at the 57 Varieties exhibit. He will be prepared to present new facts about baby feeding from a scientific viewpoint. On display will be the Heinz line of baby foods, including tomato juice and strained beets, prunes, tomatoes, spinach, carrots, peas, green beans, and mixed vegetables. Heinz Rice Flakes and Breakfast Wheat will be shown and also Heinz Oil. Oil from the company's plant in Seville, Spain. Booth 72.

**HOFFMAN La ROCHE, INC**

Digalen Manikins to Appear

In an attractive setting in Booth 83 the manikins that have been recently appearing in THE JOURNAL A M A ads of Hoffman-La Roche will dramatize the widely accepted Roche's digitalis remedy, Digalen. In addition there will be other Roche medical aids on display for the interested physician and members of the Roche staff will be in attendance.

**IDEAL BABY SHOE COMPANY**

Results of Baby Shoe Research

To determine proper types of foot coverings for each stage in the development of the normal baby foot, months of research directed by orthopedic surgeons were conducted by the department of medical cooperation of Mrs. Day's Ideal Baby Shoe Company. The results of this and other baby shoe research will be explained by representatives and may be seen in a reference portfolio in Booth 157.

JOHN F JELKE COMPANY

Good Luck Margarine

In Booth 93 the Jelke attendant will appreciate the opportunity of discussing the food value of Good Luck Margarine. Every Jelke Good Luck product has the seal of approval of the Committee on Foods Literature in connection with the vitamin content and nutritional values of Good Luck Margarine will be freely distributed.

MEAD JOHNSON & COMPANY

Products for Infant Feeding

One of the features of the Mead Johnson & Company exhibits, Booths 119 and 120 (near the registration desks) will be a display of eight of the original Postnatal paintings that have been reproduced from time to time in THE JOURNAL. These paintings are the work of Bernhard Pollast, a famous Dutch painter of child life who is considered by authorities to rank in the same class with De Hoog, Meijer, and Israels.

etc. There will be a display of all Mead products for infant feeding including Dextrin-Maltose, Pabulum, Halfbut Liver Oil, Mead's Brewery's Yeast and Mead's Powdered Milk Products

JONES SURGICAL SUPPLY COMPANY

McIntosh Physical Therapy Apparatus
As a feature of its exhibit, the Jones Surgical Company will have a complete showing of McIntosh Physical Therapy Equipment and Accessories. All physicians are invited to stop at Booth 148 to see this apparatus and to inspect a full display of surgical instruments and supplies for physicians and hospitals.

KNOX GELATINE COMPANY

To Show Special Dietetic Uses

Visit Booths 90 and 91 and learn the growing importance of Knox Sparkling Gelatine for various dietetic purposes. Attractive dishes suitable for different diets will be on display and booklets on feeding the sick, diabetic diets reducing diets, etc. will be available. Testing samples of Knox Gelatine salads and candies will also be given free. Competent representatives will be in attendance to supply detailed information.

Attractive dishes suitable for different diets will be on display and booklets on feeding the sick, diabetic diets reducing diets, etc. will be available. Testing samples of Knox Gelatine salads and candies will also be given free. Competent representatives will be in attendance to supply detailed information.

LAKESIDE LABORATORIES, INC

Ampoule Preparations

Their Council Accepted Ampoule preparations, particularly their ampoules of Dextrose (d Glucose) 50%, will be exhibited by the Lakeside Laboratories, Inc. in Booth 180. Members of the research staff will be present to demonstrate the chemical, bacteriological, and physiological methods used to insure the purity, sterility and safety of Lakeside products.

LARSEN COMPANY

Strained Vegetables

In Booth 95 the Larsen Company of Green Bay Wis. will exhibit its complete assortment of strained vegetables consisting of nine varieties, strained unseasoned ready for use—peas, spinach, carrots, beets, green beans, prunes, tomatoes, vegetables with cereal and beef broth, and celery (an exclusive item with Larsen). Particularly interesting is the fact that these vegetables are packed in protective enamel-lined containers with special vacuum seal, yet retail at ten cents.

LEA & FEBIGER

To Show Important New Works

Among the important new works to be exhibited by Lea & Febiger in Booth 60 are Atkinson's 'External Diseases of the Eye', Feinberg on 'Allergy in General Practice', Grafe on 'Metabolic Diseases and Their Treatment', Well's 'Neuropathology', and Bridges' 'Dietetics for the Clinician'. New editions of important works will include the sixth edition of Kanavel's 'Infections of the Hand', the fourth edition of Ormsby's 'Diseases of the Skin', the second edition of Nicholson's 'Laboratory Medicine', the third edition of Fishberg's 'Hypertension and Nephritis', the fifth edition of Joslin's 'Diabetic Manual', the second edition of Massie's 'Surgical Anatomy', and the tenth edition of Park and Williams' 'Pathogenic Micro-organisms'.

LEDERLE LABORATORIES INC

Biological and Pharmaceutical Products

Among their more important biological and pharmaceutical products shown by the Lederle Laboratories in Booth 53, will be Pollen Antigens, which for 20 years have proved successful in controlling hay fever attacks. Polson Ivy Extract in almond oil for Rhus Dermatitis. Antipneumococcal Serum for pneumonia, the single dose Toxoid for diphtheria prevention. Tetanus-Gas Gangrene Antitoxin for prophylaxis. Staphylococcal Toxoid, Solution Liver Extract Parenteral, Solution Liver Extract Oral, Ferric Ammonium Citrate in capsules, Cod Liver Oil Concentrate Tablets, and standardized Whole Leaf Digitalis Tablets. Attendants will gladly answer in detail the questions of visitors.

LEPEL HIGH FREQUENCY LABORATORIES INC

New Short Wave Machine

In Booths 137 and 138 the Lepel High Frequency Laboratories will exhibit their new short wave machine for local heat treatments without application of metal electrodes and a complete line of high frequency machines for electro medical and electro surgical use. A model will be shown which enables giving diathermy treatments with almost complete elimination of radio interference. They will also show a new ultra-violet quartz lamp.

ELI LILLY AND COMPANY

To Show Graphs and Transparencies

Graphs and transparencies displayed in art glass panels will be the dominant feature of the Lilly exhibit in Booths 74, 75 and 76. Among the products illustrated will be Insulin (Insulin, Lilly), Amytal Sodium Amytal, Merthiolate, Extralin, Ephedrine preparations and Biologals. The Insulin (Insulin, Lilly) panel will show the relation between the metabolic load and metabolic capacity in normal and diabetic individuals. The Ephedrine panel will illustrate certain physiological effects of this alkaloid. Physicians from the medical department of Eli Lilly and Company laboratories will be at the exhibit.

LINDE AIR PRODUCTS COMPANY

Economy in Oxygen Therapy

The Linde Air Products will feature a model oxygen tent and will give practical instruction and demonstration in the technique of testing oxygen and carbon dioxide concentrations. On display will be cylinders of Linde Oxygen USP for use with any oxygen administering equipment, the new Linde Oxygen Flow Indicator and other oxygen apparatus. Reprints of current literature on oxygen therapy will be available to those interested in the subject. Booths 143 and 144.

J B LIPPINCOTT COMPANY

"Post Graduate Instruction at Home"

Among the books to be shown by The J B Lippincott Company in Booth 135 will be Peham and Amreich's 'Operative Gynecology', 2 volumes extensively illustrated to show each operation step by step. Kirschner's 'Operative Surgery' in 2 volumes a new edition of Lippincott's 'Quick Reference Book', Lewellyn F. Barker's new 'Treatment of the Commoner Diseases', and the new idea in personal post-graduate instruction at home supplied from the Pittsburgh Diagnostic Clinic as a supplement to the 'International Clinics' and in the nursing field an entirely new work by

Solomon on "Pharmacology Materia Medica and Therapeutics for Nurses" and new editions of the standard nursing texts.

MACMILLAN COMPANY

To Show Advance Proofs

On display at the Macmillan Booth, 81, will be Crile's 'Diseases Peculiar to Civilized Man' and Pemberton-Osgood's 'Medical and Orthopaedic Management of Chronic Arthritis' which have just been published. There will be advance lithograph plates from Wilmer's 'Atlas of the Eye' which will be published some time this summer. Advance material on Meigs' 'Tumors of the Female Pelvic Organs', Miller's 'Tuberculosis of the Lymphatic System', Wilensky's 'Osteomyelitis' and other important books in preparation will also be available. Ask the representative at the booth to show you some of the latest Macmillan publications in varied fields.

MALLINCKRODT CHEMICAL WORKS

To Show the "Famous 84"

A survey has shown that nearly all prescriptions are filled from approximately 84 chemicals. Mallinckrodt, in Booth 84, will display these chemicals known to retail druggists throughout the country as "the famous 84". In addition they will show Barium Sulphate for x-ray of the gastro-intestinal tract, Jodelkon and Iso-Jodelkon radiopaque dyes permitting x-ray of the gall bladder the arsenicals, and ether for anesthesia. Films will show the first public demonstration of surgical ether anesthesia and its manufacture. Interesting literature on these items will be available to visitors.

MALTINE COMPANY

Results of Vitamin A Study

Charts and slides are to be exhibited by The Maltine Company in Booth 132, showing the results of a study just completed at one of the large Eastern universities. This demonstrates how the value of vitamin A of cod liver oil may be enhanced when it is emulsified with Maltine. The various steps in the manufacture of Maltine with Cod Liver Oil, together with photomicrographs of the final products, are also to be illustrated and described.

MARCELLE LABORATORIES

Non Allergic Cosmetics

If you will register at Booth 207, the Marcelle Laboratories will mail you any Marcelle Cosmetic item you select. Experienced attendants will be on hand to give you such information as you may desire concerning these non-allergic cosmetics.

MEDICAL BUREAU

For Medical Personnel

In Booth 121 Miss Burnice Larson will offer the facilities of The Medical Bureau, an organization acting as counselor in problems of medical personnel to hospitals, administrators, clinic managers and executives in the medical field. The records of physicians who have specialized in various branches of medicine men and women interested in assistantships, accredited graduate nurses, laboratory technicians and dietitians are available to those interested in the completion or reorganization of their staffs.

MEDICAL CASE HISTORY BUREAU**To Show Inexpensive Method**

If you find record keeping an onerous task, if you are interested in a system that shows at a glance the case you want, how many calls you made and when, the patient's history, the developments diagnosis and treatments, and the financial status of each case, it will pay you to spend some time in Booth 34 for the purpose of investigating the Medical Case History Bureau. All the charts will be shown there for all branches of medicine just as they are actually kept in their cabinets.

MEDICAL PROTECTIVE COMPANY**"The Doctor and the Law"**

In Booth 36 you may obtain a copy of the current number of the Medical Protective Company's publication "The Doctor and the Law." Under that title the law department of the Company is now presenting periodical discussions of the fundamental principles of law in their practical every day application to the practice of medicine.

MELLIN'S FOOD COMPANY**Basic Principles of Mellin's Food**

Since the adjustment of the diet for babies deprived of human milk must always be of interest to physicians, the Mellin's Food Company will set before physicians the basic principles of Mellin's Food, with the sincere belief that the evidence accumulated from long experience fully justifies the recognition of the value of Mellin's Food as a modifier of milk in infant feeding. Physicians are cordially invited to visit Booth 62.

WM S MERRELL COMPANY**Dioramas to Present Contrasts**

In Booth 42 the Wm S Merrell Company will feature two dioramas or miniature reproductions. One will depict the original apothecary shop of Wm S Merrell as it appeared in 1828, and the other an interior view of the present day Merrell Biological Research Laboratory at Reading, Ohio, making a striking comparison of the older methods of production with the up-to-date equipment of a modern biological plant. The Merrell Company will show Thibogen and Natural Sodium Salicylate as well as the standard USP and NI pharmaceuticals.

MIDDLEWEST INSTRUMENT COMPANY**Waterless Metabolism Apparatus**

The Midwest Instrument Company will feature a waterless type of metabolism apparatus with calculations eliminated by use of a very simple slide rule. Demonstrations of the technique and accuracy of the machine will be made on actual cases, and tests made without charge on anyone wishing to know his own basal metabolic rate. You are cordially invited to visit Booth 52.

**C V MOSBY COMPANY****To Show Complete Line**

A cordial invitation is extended to all physicians to visit Booth 92 where the C V Mosby Company will display its complete line of medical publications. Among the newer books to be shown will be Hertzler's "Surgery of a General Practice," Hey and Conwell's "Management of Fractures, Dislocations and Sprains," Pottenger's "Tuberculosis in the Child and Adult" and Vebers "Spinal Anesthesia."

V MUELLER & COMPANY**Hospital Equipment**

A bone surgery engine of a new design to be shown by V Mueller & Company in Booths 124 and 125 has several features that you will be interested in seeing demonstrated.

This firm will also display its new Herb-Mueller Ether Vapor and Vacuum Apparatus, which has all the latest improvements and is up to the Mueller high standard of quality. Many new patterns of surgical instruments, as well as hospital equipment, will be exhibited.

NATIONAL CARBON COMPANY, INC**To Show Milk Irradiation**

The exhibit of National Carbon Company, Inc., Booths 143 and 144, will feature the application of the Eveready Carbon Arc Irradiation Unit to the irradiation of milk. This method of increasing the vitamin D content of milk has been adopted by several of the large dairy companies in various cities and is a subject of considerable interest to all physicians. Actual irradiating equipment in full operation will be demonstrated. Competent men will be in attendance at the exhibit to explain the details of the process and the value of the resulting product.

NESTLE'S MILK PRODUCTS, INC**New Modifier of Cow's Milk**

Hyline the new modifier of cow's milk for infants, will be featured in the exhibit of Nestle's Milk Products, Inc., in Booth 61. Physicians interested in the adaptation of fresh cow's milk for infant feeding will have an opportunity to familiarize themselves with this new modifier, which makes it possible to naturalize the artificial feeding in proportions of fat, carbohydrate and protein. Representatives in charge of this exhibit will gladly supply detailed information on Hyline to all physicians who visit the Nestle booth.

OHIO CHEMICAL AND MANUFACTURING COMPANY**Complete Line of Anesthetic Gases**

In Booth 179 The Ohio Chemical and Manufacturing Company will exhibit a complete line of Ohio anesthetic gases showing a new and better cylinder seal and a new rubber grip for large cylinders. They will also show oxygen therapy apparatus which is now available for rent or for sale through 17 branches located in principal cities. Another interesting item will be Deuterium Oxide (Heavy Water), the new element which has created so much interest in the field of scientific research. Ask to see Ohio Ethyl Chloride and the new Carrying Alt.

PAGE MILK COMPANY**Vitamin D Evaporated Milk**

You are invited to stop at Booth 179 to get full information concerning Page Vitamin D Evaporated Milk. This milk is not irradiated, the vitamin D being obtained by the addition of a tasteless cod liver oil concentrate. Each tall 142-ounce can contains 150 Steenbock units of vitamin D. Because of its unusually high vitamin D potency and because the use of this same concentrate doubles the normal vitamin A content, Page Vitamin D Evaporated Milk is of particular interest for infant feeding. It may also be used in puddings, custards, etc., as cooking does not affect the vitamin potency.

**LYDIA O'LEARY****A Way to Conceal Birthmarks**

Practically every physician encounters persons who are handicapped by the presence of unsightly birthmarks on the face, neck or arms. How these blemishes can be so expertly concealed as to practically defy detection will be shown by Lydia O'Leary in her demonstration of "Cover Mark," a harmless preparation which needs to be applied but once a day. The preparation resists water when swimming and will not crack or rub off until removed. A

visit to this demonstration may help you remove an overwhelming handicap from some of your patients or acquaintances. Booth 209.

OXFORD UNIVERSITY PRESS**Invites You to Browse**

The Oxford University Press feels that a few minutes of your time browsing in its exhibit in Booth 49 will be well spent. It will contain many books of interest to the general practitioner and the specialist, such as the new edition of "Applied Physiology" by Wright, "A Text-Book of Psychiatry" by Henderson and Gillespie, Mayou's "Diseases of the Eye" revised by Ridley, and others of equal importance.

PANDORA BAG COMPANY**To Show Bag in Construction**

The new Pandora Bag in all stages of construction just as it is made at the factory, will be shown by the Pandora Bag Company in Booth 169. Physicians can learn

how the bag is made, examine samples of the leather, see all the sizes, and determine whether Pandora fits their needs. The new ampoule case bottle arrangement meets of every variety the new hypodermic case which makes blunt needles an impossibility, and the new sterilizer which makes your Pandora into an OB bag at will—all fitted to Pandora—will be shown.

PARKE, DAVIS & COMPANY**Demonstrations by Research Workers**

An exhibit of unusual scientific interest is being prepared by Parke, Davis & Company. Apparatus used in the standardization of pituitary hormones will be included. In the exhibit and actual demonstrations will be made to visiting physicians by research workers from the Parke-Davis Laboratories. Among other things to be shown is the new barbiturate hypnotic Oral Sodium, which has aroused widespread medical interest because of its high efficiency and low toxicity. Expert technical men will be in charge to welcome you to Booths 30, 31 and 32.

**E L PATCH COMPANY****Flavored Cod Liver Oil**

Throughout the past few years when the vitamin picture has been constantly changing, Patch's Flavored Cod Liver Oil has maintained its high position as a natural source of vitamins A and D. This year, in Booth 57, there will be some new and interesting features in connection with this well known product. The Patch Laboratory representatives will be on hand ready to answer questions and give information regarding the latest developments in the production and use of cod liver oil.

**PATTERSON SCREEN COMPANY****New Screen Will Interest Roentgenologists**

The Patterson Screen Company will exhibit their products in Booth 184 where Mr. Patterson and Mr. Reuter will be in attendance. See the new type B fluoroscopic screen which was introduced late last year, and learn of its advantages.

PETROLAGAR LABORATORIES INC
New Product with Cascara

Petrolagar with Cascara, a new product for the treatment of constipation which combines the mechanical softening action of Petrolagar-Pain with the stimulating effect of Fluidextract Cascara Sagrada will be exhibited by Petrolagar Laboratories Inc, in Booths 2, 3 and 4. There will be a continuous showing of Petrolagar Scientific Medical Motion Pictures and an exhibition of photographs of notable physicians who have offered major contributions to medicine.

GEORGE P. PILLING & SON COMPANY
Instruments for Thoracoplasty

Bronchoscopic and esophagoscopic instruments as developed by the staff of the Chevalier Jackson Clinics will as usual be featured in the exhibit of George P. Pilling & Son Co., Booth 108. Special attention will also be directed to instruments used

in the rapidly developing field of thoracoplasty, and instruments of Sauerbruch, Frey, Schneider, Lebsche, Alexander, Bethune, Hudson, Honan and O'Brien will be shown. Brain surgery instruments and recent developments in rectal and oral surgery will also be displayed. Pilling and Company make many of these instruments in their own factory, and invite you to inspect them.

W. F. PRIOR COMPANY
Loose Leaf Sets

Its latest 3-volume loose-leaf sets, 'Gynecology and Obstetrics' and 'Principles and Practice of Physiotherapy' by Mock, Pemberton and Coulter, will be featured by the Prior Company. In the latter book this most misunderstood subject is assessed by men high in medical ranks. Its essential dovetailing with proper medical and surgical treatment with restoration of function as the goal, is covered in an unbiased manner. See also Dean Lewis' 'Practice of Surgery' and Tice's 'Practice of Medicine' in loose-leaf form. Booth 56.

RADIUM CHEMICAL COMPANY, INC
and
RADON COMPANY INC
To Have Joint Exhibit

New types of containers and accessories for the application of radium and radon in malignant and non-malignant conditions will be displayed by the Radium Chemical Company, Inc and the Radon Company Inc in Booth 187. Attention is called particularly to the display of the new removable platinum radium cells, with complementary gold sheath needles (for interstitial irradiation) and platinum capsules (for intra-cavity application). With a small quantity of radium in these removable cells, the same type of effective work can be done as with a larger amount of radium made up into containers of more permanent form.

RALSTON PURINA COMPANY
Cereals and Ry Krisp

Ralston Wheat Cereal, Baby Ralston and Ry-Krisp, the Whole Rye Wafer, will be

exhibited by the Ralston Purina Company in Booth 35. Ralston Wheat Cereal provides the elements of whole wheat plus the appetite-essential properties of the extra vitamin B, added in the form of wheat germ. Baby Ralston now furnishes a rich source of vitamin B, iron and calcium for the small infant who is just starting to eat cereal. Ry-Krisp, which remains the country's most popular rye cracker is used in general as well as special diets. The exhibit will afford an excellent chance to learn about these three important food products.

SMA CORPORATION

Antirachitic Breast Milk Adaptation

SMA, the well known antirachitic breast milk adaptation for infants deprived of breast milk, will be featured in the display of the SMA Corporation. SMA, when diluted according to directions, is essentially similar to human milk in percentages of protein fat, carbohydrate and ash, in chemical constants of the fat and in physical properties. Powdered Hypo-Allergic Milk for the milk-sensitive will be another feature—ask for the 'Milk Allergy' booklet. Alerdex, the protein-free maltose and dextrins, product which is gaining favor for routine use as a prophylactic against cereal eczemas, will also be displayed in Booth 82.

**SANBORN COMPANY**

Metabolism and Electrocardiograph Testing

The 1934 Sanborn Motor-Graphic Metabolism Tester, introducing the electrically driven kymograph clock, will be on display in Booth 64. You are invited to inspect this tester, and also the 1934 Sanborn Electric-Portocardiograph which operates directly from lamp socket or wall plug. This makes it a conveniently portable outfit for testing at patients' homes, as well as for office use.

SCANLON MORRIS COMPANY

To Demonstrate New Operating Table

For the first time Scanlon-Morris Company will demonstrate its latest general operating table, which incorporates remarkable conveniences for general and special surgery. New features in dressing water, instrument and utensil sterilizers that greatly simplify control of the sterilizing process will be available for investigation. Specialties in suture materials will be demonstrated and a novel glove-drying and powdering machine will be exhibited. An experienced representative will be in attendance at Booth 12 to discuss equipment problems of the surgeon and the hospital executive.

W. B. SAUNDERS COMPANY

Books That Describe New Treatments

An examination of the books to be shown by W. B. Saunders Company in Booth 63 will reveal the vast number of new treatments, both medical and surgical, that have come into practice even during the past year. Particularly important are Curtis 3-volume 'Obstetrics and Gynecology', Callender's 'Surgical Anatomy', Beckham's 'Operative Surgery', the new Mayo Clinic Volume, Beckham's 'Treatment', De Lee's 'Obstetrics', Cecil's 'Medicine', 'Medical Clinics of North America' and 'Surgical Clinics of North America', Stokes' 'Syphilology', Pepper and Farley's 'Hematologic Diagnosis', Buck's 'Physical Diagnosis', Gleason on the 'Nose, Throat and Ear', Jackson's 'Bronchoscopy', Esophagoscopy and 'Gastroscopy', Norris and Landis 'Chest Diseases' and Griffith and Mitchell's 'Pediatrics'.

**SANOOZ CHEMICAL WORKS INC**

Outstanding Pharmaceutical Specialties

Sandoz Chemical Works, Inc., will feature Calglucon (Calcium Gluconate-Sandoz) in stable ampule solution for safe, non-irritant intravenous and intramuscular calcium therapy, also in tablets and granules for palatable oral use. In addition they will present Gynergen, the original product containing the specific ergot alkaloid, ergotamine, in pure and stable form, and Scilifaren, the glucosidal principles of squill, a new and reliable cardiodiuretic. Competent representatives will be in attendance at Booth 71.

SCIENTIFIC SUGARS COMPANY

New Carbohydrate Syrup

Cartose, the new carbohydrate syrup for supplementing milk for infant feeding, will be displayed by the Scientific Sugars Co. in Booth 159. The constant uniformity, the remarkable bacteriological purity and the economy of this maltose-dextrin-dextrose-sucrose product appeal to the exacting pediatrician as well as the general practitioner.

SHARPE & DOHME, INC

Will Make Exhibit Different

Sharpe & Dohme will occupy Booth 112 this year, and their exhibit is expected to be entirely different from any which they have ever had. No particular pharmaceutical or biological product will be displayed, but their exhibit will be attractive and interesting and will be well worth visiting.

SHARP & SMITH

Large Display of Instruments

In addition to a complete line of surgical instruments and supplies as regularly exhibited by Sharp & Smith, there will be on display in Booth 25 the Willamac Electrode with various tips suitable for every kind of work in diathermy.

SNUGGLE RUG COMPANY

Infants' Crib Covers

In addition to the Snuggle Bunny and Snuggle Duck, Crib Covers for infants which the Snuggle Rug Company has been

manufacturing for several years some new Crib Covers will be demonstrated in Booth 103. Each of these keeps the baby completely and comfortably covered at all times, and at the same time allows him complete freedom of movement under the cover. You are invited to inspect this line of Crib Covers which answers most of the infant sleeping problems, including all pocketbooks, climates and seasons.

SPINACH PRODUCTS COMPANY

Spintrate in New Form

The demand for an easier method of administration with adults and older children has resulted in the development by the manufacturers of Spintrate during the past year of candy coated Spintrate tablets. Doctors interested in organically bound mineral supplements to special diets are invited to become acquainted with this new item at Booth 87. The powdered Spintrate as used in infants' formulae will also be demonstrated.

SONOTONE CORPORATION

To Demonstrate Hearing Aids

Latest developments in bone conduction hearing aids for individual and group use will be demonstrated by the Sonotone Cor-

poration, Booth 211 This is an opportunity to inspect and test personally devices which have attracted wide attention in recent months Vacuum tube equipment for individual or group use, including the set for teaching purposes with audiometer attachment will also be on exhibition Interesting literature containing complete information on Sonotone products will be supplied for your files

SPENCER CORSET COMPANY

To Demonstrate Support

The Spencer exhibit in Booth 115 will interest both physicians and their wives.

Trained representatives will demonstrate the Spencer theory of individual designing service, which transfers the pull of the abdominal support to the pelvic girdle and not to the spine at or above the lumbar region. They will explain the advantages of having supports individually designed to meet the particular needs of each patient, and will display and demonstrate supports for post-operative wear, maternity, post-partum, sacro-iliac sprain, movable kidney, enteropneosis, hernia, and breast uplift.

E. R. SQUIBB & SONS

New Liver Preparation

An extensive exhibit occupying Booths 79 and 80 will be utilized by E. R. Squibb & Sons to acquaint visiting physicians with the new developments in their glandular, anesthetic, vitamin, chemo-therapeutic and biological products. One of the new products to be featured is Autolyzed Liver Concentrate. The display of Pollicen Extracts will attract physicians who are interested in any fever therapy. Competent attendants will be present to answer inquiries and discuss any Squibb products.

STOKELY BROTHERS & COMPANY

Introduce Strained Foods

Growers and canners of vegetables for 36 years, Stokely Brothers & Company are introducing their new Strained Foods for Baby. They will show why every step in the preparation of these foods is laboratory controlled from the moment the fresh vegetables and fruits go into the shays, glass lined kettles until they are sealed in special golden enamel lined cans, and how the natural flavor, valuable vitamins and mineral salts of the fresh product are retained to a high degree. Visit Booth 156 and see why these foods are so tempting to baby.

SURGICAL PUBLISHING COMPANY

'Surgery, Gynecology and Obstetrics'

Edited and published by surgeons in the interest of practitioners of surgery, this journal, "Surgery, Gynecology and Obstetrics" will be exhibited by its publishers The Surgical Publishing Co. in Booth 173. It presents monthly a score or more of original contributions by eminent authorities and provides a complete and authoritative résumé and index of the current surgical literature of all languages. See also Dr. Franklin H. Martin's autobiography "The Joy of Living" which will be on display.

SUN RAYED COMPANY

Kemp's Sun Rayed "on Draught" Again
Kemp's Sun-Rayed Pure Tomato Juice will again be "on draught" in Booth 51 with the compliments of the manufacturer the Sun-Rayed Company, Division of Kemp Bros. Packing Company. Attention will be called to the patented manufacturing process by which whole vine-ripened tomatoes are converted into fruit-bodied, non-separating juice and to the exacting methods of vitamin retention. New photographs will illustrate the production process and a new trophy awarded the Kemp Brothers will be displayed.

TAYLOR INSTRUMENT COMPANIES

Sphygmomanometers and Thermometers
Along with Tyco's Sphygmomanometers, the Taylor Instrument Companies' exhibit will feature the new Taylor Estee Thermometer. This high grade clinical thermometer will be offered at an extremely low price singly or in professional sets of six. The set consists of any combination of bulb styles desired, oral, rectal or stubby. Booth 98.

Taylor

CHARLES C. THOMAS

Will Show New Books

Of special interest in the Charles C. Thomas exhibit Booth 1 will be Moore's "Modern Treatment of Syphilis," Grinker's "Neurology," Carlisle's "Practical Talks on Heart Disease," Thomas's "Clinical Pathology of the Jaws," Dandy's "Benign Tumors in the Third Ventricle of the Brain," Glasser's "Science of Radiology," Glasser's "Wilhelm Conrad Röntgen," Fischer's "Lymphatic Collapses," Roman's "Surgery" (2nd edition), Hitchcock's "Physical Chemistry," Blech and Lynch's "Medical Tactics and Logistics," Kanner's "Child Psychiatry," Craig's "Amoebic Dysentery," and Wiener's "Blood Groups."

TRAINING SCHOOL AT VINELAND

To Show Work in Research Laboratory

The Training School at Vineland N. J., a private school for mentally deficient children and adults will display hand work of some of its pupils in Booth 50. Miss Clarrette Sehon, field secretary for the institution, will be in charge of the exhibit. She will show moving pictures of the work being done particularly in the research laboratory of the Training School where the causes of mental deficiency and the means of ameliorating the condition of the mentally deficient are being sought. Literature giving full information concerning the school will be available.

UNITED FRUIT COMPANY

Drink a Ripe Banana

At the exhibit of the United Fruit Company, Booth 41 you may enjoy a variety of delicious drinks made from fresh ripe bananas before your very eyes. Printed recipe cards showing the methods and ingredients for making these banana drinks, will be distributed. In addition the latest scientific data on the nutritive and therapeutic value of the banana based on extensive research, will be supplied.

UNITED PRUNE GROWERS

To Refute Misleading Ideas
The results of two years of extensive research proving the falsity of many ideas concerning prunes are being published by the United Prune Growers for distribution.

In Booth 67 The exhibit will be presided over by Ray Randall and L. B. Williams of the California Dried Fruit Research Institute, and E. M. Mtrak of the University of California.

VITAMIN FOOD COMPANY

Animals to Feed on Vegex

The chemist who made the first salt enzyme autolyzed extract from yeast Vegex found that it tasted like cooked meat, although meat-free. Vegex was widely used for soups before the vitamin discoveries. During the World War the British government selected it for treating beri-beri and then for the regular rations of the troops. Since then in medical centers with both child and adult diets Vegex has been a standard for Vitamin B₁ and is equally high in Vitamin G or B₂. See the 90 or more animals on vitamin feeding tests in the Vegex exhibit in Booth 203.

WINTHROP CHEMICAL COMPANY INC

AND H. A. METZ LABORATORIES

Pharmaceuticals of Note

All visitors are cordially invited to inspect Booths 99 and 100 where, among the many outstanding products to be displayed attention will be called to Salyrgan, the diuretic whose value is universally recognized, Phantodorm, the hypnotic which assures natural sleep without a "hang-over", Sklodan, for intravenous and retrograde pyelography, Silver-Salvarsan, of proved efficiency in resistant types of syphilis and to other well known products. Literature on these preparations as well as on newer introductions will be freely available to all physicians.

WILLIAM WOOD & COMPANY

and

WILLIAMS & WILKINS COMPANY

Find New Strength in Union

Booth 17 will represent the union of one of the oldest and one of the youngest American publishing houses—William Wood & Co. and the Williams & Wilkins Company—and will provide a convenient opportunity for you to examine their latest medical and scientific books and journals. Included will be many new editions of well known standard works, such as Cabot's "Physical Diagnosis," Delafield & Prudden's "Pathology," May's "Eye, Ear, Nose, Throat," Keith's "Embryology," and others also such striking new books as Dickinson's "Human Sex, Anatomy and his The Single Woman."

CARL ZEISS INC

Call Attention to Photometers

Their well known microscopes and accessories, as well as other scientific and surgical apparatus, will be shown in Booth 113 by Carl Zeiss, Inc. You are especially invited to see the Pulfrich Photometer for colorimetric and nephelometric examinations, the Wolf-Schneider flexible Gastroscope, the Laparo-Thoroscope for severing adhesions and the Birch-Hirschfeld Retinal Photometer for determining vitamin A deficiency.

ZIMMER MANUFACTURING COMPANY

New Fracture Bed to Be Shown

An interesting assortment of the newest items in fracture equipment will be displayed by the Zimmer Manufacturing Company in Booth 97. A model of the fracture bed with overhead frame that has been officially approved by the Fracture Committee of the American College of Surgeons, the new Roger Anderson Reduction Apparatus, the Electric Plaster Cutter and other items will be shown for the first time.

SATURDAY, MAY 12, 1934

THE CLEVELAND SESSION

As will be apparent to every Fellow of the American Medical Association who considers carefully the material available in this issue concerning the Cleveland session, the scientific pabulum there offered will be nourishing. The scientific exhibits surpass in number and equal in quality those of previous sessions. In the clinical programs, the Council on Scientific Assembly and the officers of the sections have provided a series of general scientific meetings in which leaders of note will discuss topics of immediate interest to the entire assemblage. The scientific sections of the Association, which cover all the leading fields of medical practice, will be supplemented by special sessions of the Section on Miscellaneous Topics devoted to medicolegal problems and to questions on nutrition. Coordinating the scientific presentations, the sections will be fully represented in the Scientific Exhibit, as will also the general scientific meetings.

The policies of medical science and of the practice of medicine in relationship to the public and the state will have thorough consideration at the Cleveland session. Not only will these come before the House of Delegates in the routine manner—as was made apparent by the report of the Board of Trustees and of the special councils, published in *THE JOURNAL* last week—but also a special session of the House of Delegates in executive session is planned for special consideration of problems of medical economics. A thorough consideration in this democratic assemblage of the elected representatives of the medical profession in all the states and territories should yield policies by which the medical profession may be guided in these changing times.

The medical profession of Cleveland is doing its utmost to plan a program of entertainment, an opening meeting, and a number of receptions and banquets which are in accord with the repute of that city for hospitality. The number of reservations made at the leading hotels in Cleveland indicate a record breaking attendance. *THE JOURNAL* would therefore advise those who contemplate attending the session to make their

reservations at the earliest possible moment in order to be assured of comfortable quarters.

The city of Cleveland situated on one of our great inland lakes, is in the month of June one of the most comfortable cities of America. It is easily accessible to every type of transportation. The session comes at a time that seems to mark the beginning of the end of the economic depression. The physician who has at heart not only his scientific advancement but also the needs of his profession will do his utmost to participate in the Cleveland session.

THE PROBLEM OF HUMAN STERILIZATION

Alarm over the apparent increase in crime and the financial burden of institutionalization of social enemies and incompetents has renewed interest in ways and means of solving this problem. Human sterilization, at present receiving its test in a mass effort in Germany,¹ is perhaps the principal method being studied at the present time. In this question the medical profession is directly interested as the instrument for carrying out any such program, and indirectly as an important division of society in deciding if, how and why any large scale attempts at human sterilization should be attempted.

As to the importance of the burden of crime, insanity and feeble-mindedness to society there can be but one answer. In the United States² the number of patients with mental disease resident in state hospitals alone has shown a marked increase. In 1880 there were 31,973, in 1910 there were 159,096, and in 1929 there were 272,527 patients with mental disease confined in state hospitals. Further analysis of these statistics is necessary. The ratio of total patients with mental disease per hundred thousand of the general population increased from 63.7 in 1880 to 225.9 in 1929. Again analysis is insufficient, is the increase real or due to a higher percentage of institutional confinement in recent years? What proportion of these patients are suffering with "inherited" mental disease? Viewing the problem from a slightly different angle brings out further matter for consideration.³ "Careful studies indicate there are six millions in the United States who have been, are now, or at some future time will be legally committed as insane to state institutions.

There are six million additional cases who are not mentally diseased, but who are so deficient in intellect with an endowment in this respect that is more than 50 per cent below average that they are often described as feeble-minded." The financial cost is difficult to analyze in all its direct and indirect ways. Suffice it to state by way of illustration that the per capita cost in 1928 for prisons was \$320.89, for hospitals \$308.85, and for institutions for

¹ Human Sterilization in Germany and the United States editorial J A M A 102 1501 (May 5) 1934

² Landman J H Human Sterilization New York Macmillan Company 1932 pp 16 17

³ Randall H E The Operation of Sterilization J Michigan M Soc 33 74 (Feb) 1934

the feebleminded and the epileptic \$300 67⁴. The facts and figures of the growing burden of social misfits and incompetents could be multiplied. Certainly there is no doubt of the social and economic problem.

Sterilization of the unfit as a means of gradually reducing the toll exacted from society is not of recent origin. It is based on the essential concept that certain traits which are recognized as unsocial are perpetuated in the race by direct propagation. It is on this concept that the whole problem hinges. When viewed superficially with only cursory examination of the eugenic evidence, few socially minded individuals can resist the rosy outlook of banishing incompetence in a few years by the simple expedient of preventing the conception of such individuals by sterilization of the potential parents. The laws governing human heredity, especially of "mental traits," are unfortunately not known. Too often a mental trait is confounded with a mendelian unit character. Too often are uncritical histories of families such as the Jukes, the Kallikaks and the Edwardses the basis for unsubstantiated far-reaching eugenic conclusions. In feeble-mindedness, schizophrenia, circular insanity, epilepsy, Huntington's chorea and hereditary blindness and deafness the proponents of eugenic sterilization find evidence of inheritance which they believe amenable to reduction by this means. Other authorities however (e.g., Tredgold⁵), believe that mental deficiency is not due to absence in the ancestral germ cells of certain components but to incomplete development resulting from diminished capacity of growth of the seed. Tredgold finds moreover, that the proportion of defectives who are the offspring of defective parents is exceedingly small. It follows that, if every defective in existence a generation ago had been sterilized the number of defectives today would not be appreciably diminished. Hence if this principle should be properly applied it would be necessary to sterilize heterozygous individuals who are latent carriers of mental ailments.

From the evidence thus briefly considered it would appear that society is faced with an increasing (so far) load of mental and physical incompetents. Whether sterilization of large numbers of these incompetents would improve the position of society is dependent on one of two factors as yet undetermined. If it becomes possible to gage the laws of human inheritance with mathematical certainty, either human sterilization or "positive eugenics" (increased breeding of desirable stocks) would seem desirable. If, on the other hand without waiting for more definite information of inherited transmission, mass sterilization of defectives is carried out, with subsequent definite decrease in the number of defectives, its value also would be proved. Such a program could not, however, be subject to critical analytic conclusions short of several generations.

AN INVESTIGATION INTO THE CAUSE OF HYPERTENSION

Since 1733, when the English rector Stephen Hales published the results of his ingenious experiments "to find out the real force of the blood in the arteries," this subject has occupied the attention of medical men. Lifetimes of study have been devoted to elucidation of the intricate problems of cardiovascular physiology and pathology, clinical applications have kept pace. But efforts directed to the determination of the causes of the so-called degenerative circulatory diseases, and to the discovery of effective treatments, have met failure at almost every turn. Of late years, indeed, these conditions, whether by reason of better diagnosis, greater population of susceptible age groups or other changes, appear to be increasing in frequency.

It is with more than usual interest, then, that one reads of the experiments of Goldblatt and his collaborators¹ at Western Reserve University. These investigators report, for the first time, the successful production of persistent arterial hypertension in animals, this was accomplished by establishing chronic reduction of the flow of blood to the kidneys. Eleven healthy dogs were prepared with one carotid artery looped through a short tube of skin after the method of Van Leeuwen to permit accurate observations of blood pressure at frequent intervals, blood and urine examinations were made to rule out the presence of renal disease. Systolic blood pressure readings were taken daily for at least two months to establish control levels, the animals were then operated on under aseptic conditions, and adjustable silver clamps were applied to the renal arteries. In some of the animals constriction was made great at the beginning, while in others it was made moderate at first and subsequently increased one or more times. Constriction of one renal artery was followed by a moderate or slight rise of pressure, which tended to return to the level of the control period. Following the production of bilateral renal ischemia, however, the systolic blood pressure rose to a variable degree in all the animals. Pressures persisting between 200 and 240 mm. of mercury were common, some approached 300. In two of the animals the clamping of both renal arteries was made almost complete from the beginning, the rise of blood pressure that followed was accompanied by the development of uremia, which rapidly proved fatal. In these animals the amounts of urea nitrogen, total nonprotein nitrogen and creatinine in the blood increased progressively, while the urea clearance and the output of phenolsulphonphthalein decreased progressively until death. The remaining animals survived for long periods with large persistent elevations in blood pressure, five of them being alive at the end of fifteen months, in only a few of these nine did tests reveal any decrease in kidney function. In one animal showing a persistent elevation of blood

¹ Goldblatt, Harry, Lynch, J., Hanzal, R. T. and Summerville, W. W. J. Exper. Med. 59:347 (March) 1934.

pressure for more than fifteen months, the urea clearance was reduced to about 50 per cent of the mean control level. In others, however, either no change occurred in urea clearance or only slight preliminary reduction, with rapid return to normal. The concentrations of urea, total nonprotein nitrogen, creatinine and guanidine in the blood all remained within normal limits.

Goldblatt and his associates also investigated the effects of constriction of the splenic and both femoral arteries in one animal and of extirpation of one suprarenal gland with denervation and destruction of the medulla of the other in a second dog; neither of these procedures had any significant effect on blood pressure, which then rose in both instances after constriction of the renal arteries.

Ischemia limited to the kidneys appears to be a sufficient condition for the production of persistently elevated systolic blood pressure. The hypertension produced by this means resembles closely that associated either with so-called benign nephrosclerosis or with so-called malignant nephrosclerosis in man, depending on whether the constriction of the arteries is moderate or severe.

The Cleveland investigators deserve commendation for this fundamental contribution, ingeniously conceived and meticulously executed. Their work throws new light on the pathogenesis of hypertension, at least of the type associated with renal vascular disease.

Current Comment

SOCIALIZATION OF MEDICAL PRACTICE

In the department of Medical Economics in this issue of *THE JOURNAL* appears a summary of a report on the socialization of medical practice, including health insurance, made by the Bureau of Economics of the American Medical Association. The report appears in full in the *American Medical Association Bulletin*, which is sent to all Fellows. Others desiring copies of the *Bulletin* may send their requests to the headquarters office. The physician who is familiar with the history of the attitude of the American medical profession toward changes in the nature of medical practice realizes that this question has not been neglected by the House of Delegates of the American Medical Association. Immediately following the introduction of socialized medicine in Great Britain, as represented by the panel system, the House of Delegates of the American Medical Association authorized a special study of social health insurance. At subsequent meetings, the House of Delegates expressed itself in no uncertain terms relative to invasion by the state in the affairs of medicine. A few years ago it instructed the Board of Trustees and the Officers of the American Medical Association to use *THE JOURNAL* and all the facilities of the Association in opposing the introduction of state medicine in any form. That has been the assigned task of the officials at the headquarters of the

Association. Moreover, the endorsement in principle of the Minority Report of the Committee on the Costs of Medical Care at the annual session of the American Medical Association reaffirmed this policy for officials of the American Medical Association. There seem to be evidences that official bodies representing the medical profession in some of the states are interested in a change of this policy of the House of Delegates. It remains to be seen, therefore, whether the American medical profession as represented by organized medicine through the House of Delegates, wishes to continue its policy of careful experimentation with new methods of medical practice, observing the ethics and traditions of medicine or whether it is ready to endorse on a nation-wide scale some step toward the socialization of medical care. Obviously, the medical profession has never been confronted at an annual session with questions of greater moment for its determination.

SECRETION OF PANCREATIC JUICE

Thirty-two years ago the English physiologists Bayliss and Starling formulated the theory that the secretion of pancreatic juice is brought about by a humoral mechanism. According to them the entrance of gastric acid into the duodenum somehow promoted the formation or liberation of a chemical substance, designated as secretin, that is absorbed and carried to the pancreas, where it acts as a stimulus to secretion. Participation of the nervous system was excluded by the observation that the secretory phenomenon is observed even when all nervous connections between the intestine and the pancreas are severed. This classic experiment initiated the modern conception of hormone stimulation of functional organs. The fundamental features of the hypothesis have retained acceptance though the views and experiments of Bayliss and Starling have been challenged from time to time. One item for debate has been the question as to whether a prosecretin really exists, that is, whether secretin is not always present preformed in the intestinal wall. Another uncertainty has centered in the reputed necessity for acid in the initiation of the hormone reactions. Thus the English physiologist John Mellanby has suggested that, as soon as bile reaches the duodenum, bile salts are in part absorbed through its mucosa and carry preformed secretin along with them into the portal circulation. By an ingenious experiment whereby the volumes of secreted bile and pancreatic juice can be measured every day and each of them withdrawn from the alimentary tract or replaced at will, Dragstedt and Woodbury¹ of the University of Chicago have demonstrated at least for the species on which all the classic tests have been undertaken, that the presence of bile in the duodenum cannot be considered essential for the secretion of pancreatic juice. The ingestion of food even in the absence of bile promotes the usual pancreatic secretory response. In other words bile salts cannot therefore be considered essential either for the activation of the specific pancreatic stimulant or for its passage into the blood in effective form.

Medical Economics

"THE INSURANCE PRINCIPLE IN THE PRACTICE OF MEDICINE"

A Summary of a Report Prepared by the Bureau of Medical Economics

The various forms of social insurance aim to give protection against social uncertainties. Their scope is usually restricted to those whose incomes are insufficient to permit the accumulation of a reserve to meet social contingencies.

A recent German writer¹ thus describes the origin of insurance:

Social insurance is the child of its period. It is the result of a compulsory urge to organization and had its origin in the mechanical conception of life.

The increasing industrialization of Germany had need of a healthy, efficient working force for its development and the Kaiser needed soldiers.

Bismarck's original plan arose out of a combination of the capitalistic with the feudal and fraternal mental attitude. Governmental care was to make it clear to the eyes of the workers how much the state cared for them and thereby make them contented and loyal.

Austria, with much the same stage of development, followed in 1887. Other nations showed few signs of following this example during the nineteenth century. But the first decade of the present century saw a remarkably rapid expansion of sickness insurance among European states. Tables 1, 2 and 3 give the date of the introduction of such systems among the principal nations and also something of the extent of their expansion within those nations.

Sickness insurance was at first directed against the unemployment caused by sickness. All the emphasis was placed on the financial assistance given to the wage earner while sick. There was little consideration of the necessity and value of medical care.

Sickness insurance is always urged in the interests of underpaid workers, but these have never been responsible for or even highly favorable to its enactment. Laborers have rather demanded wages sufficiently high to enable the recipients to pay their own medical expenses. In no country have the unions led a demand for sickness insurance. In nearly every country the first attempt to collect sickness insurance contributions from employees has met with resistance. It was so in Germany a half century ago and in France in 1931. The political parties of labor have never made sickness insurance one of their urgent planks. No system owes its introduction primarily to any socialist or labor party.

The story of Germany is typical and has been told many times. Bismarck introduced the law as a weapon against the Social Democrats who voted unanimously against it. For years this party fought all forms of social insurance, denouncing them as a "beggars' soup kettle," from which relief was ladled out to prevent discontent. Then the Social Democrats captured the insurance societies and made them a part of their political machine, whereupon these institutions became "sacred cows" to be defended against all criticism. The benefits of social insurance, which Bismarck expected to use to buy support for the imperial government, were then used to buy Social Democratic votes.² The latest development has been the seizure of these institutions by the Nazis, who are now using them to crush out Social Democracy.

The situation was much the same in other countries. In an address to the International Conference of Insurance Societies, Dr. Winter, delegate from Czechoslovakia, said:³

Sickness insurance was introduced into the countries of Central Europe, into Germany and later into Austria at a time when the working class was largely powerless in the political field. The motives always political which led to its introduction are well known. The working class was not represented in the political institutions but it was left in control of the insurance societies.

He then describes how this control of the societies was turned into a political weapon. Of Austria we are told:⁴

The societies are the pillars of the political parties. They have been so anxious to give benefits to the insured that they are today in a miserable financial condition. In spite of the magnificent palaces they have constructed to shelter their services all this is only a deceptive show.

Great Britain repeats the story. The law was enacted as a political measure by Lloyd George, and the societies at once became political forces, antagonistic to many of the best features of insurance.

Sickness insurance has been introduced everywhere with very little consultation with, and often largely against the wishes of, the workers who were to become the patients, and the physicians who were to give the medical service.

One of the most striking conclusions that arise from any comparative historical study of sickness insurance systems is their highly experimental character. This is true of the oldest as well as the youngest systems. After a half century of existence, those of Germany and Austria are still changing with great rapidity. These changes are by no means due exclusively to general political, industrial or financial transformations, which often fundamentally alter the workings of the system. They are much more due to constant dissatisfaction with details.

This continuous tinkering creates an extremely complex set of institutions. There are 3000 sections in the German laws on sickness insurance, and this is only the beginning. The various institutions for the regulation of insurance and the settlement of disputes between contending parties within the system are making new modifications and interpretations almost daily.⁵

An examination of the column headed "Date of Enactment of Law" in table 1 will give some impression of the number of more important fundamental legislative changes in the various systems. A failure to recognize this wide diversity of time and place in the workings of sickness insurance is largely responsible for the contradictory reports and opinions expressed by those who discuss such insurance.

An examination of tables 1, 2 and 3 would supply the advocate of almost anything in regard to insurance with facts to support nearly any argument. This might appear to suggest a simple solution. It might be argued that if one were to pick out all the desirable features from each system and combine them, one might develop a perfect system. Unfortunately the problem is not so simple. Some of the desirable and undesirable features in nearly every system are so closely linked by administrative or political considerations as to make separation difficult if not impossible.

The changes that took place in the evolution of the various systems often profoundly altered their character. The early groups of fellow workers had little to fear from malingering. Members constantly visited the sick and often assisted in their care. Before sickness insurance the societies were truly self governing and sufficiently democratic to insure that their officials, who were almost always unpaid, truly represented the membership. They had no need for elaborate financial organizations or expensive headquarters.⁶

The supposition that these conditions could be carried over into the gigantic societies required for the insurance of millions is responsible for many of the evils of present systems. The claim that the great financial and semipolice organizations of paid visitors and supervising physicians with their intricate statistical reports of expenses and rate of so called sicknesses are but a larger growth of the old fraternal societies is but one of the many examples of failure to recognize that a great change in the quantity of any social phenomena almost inevitably changes the quality and character of the institutions involved.

⁴ Narbeshuber, Carl (President of the Austrian Medical Association). *Revue internationale de médecine professionnelle et sociale*. November 1925, p. 54.

⁵ The modifications of the legal institutions have been incessant in Germany, an indication of the difficulty of the social and technical problem to be solved. It is only by personal solutions, the English method of trial and error by the acceptance of an empirical progression that the best results are obtained. (Italics in original.)

† Made compulsory in October 1933

on his part "The effort toward adjustment to reality," he says "is replaced by the desire for indulgence, nursing and maintenance of the infantile situation. So we arrive at the remarkable fact that the sick seek to gain pleasure and profit from the condition of sickness and, in spite of their sufferings and burdens, basically do not wish to get well. So we speak of a flight to sickness and of a sickness advantage (Krankheitsgewinn).

Dr Blum concludes his analysis with the statement
So we arrive at the tragic fact that an institution created in response to the highest social impulses and to serve such social purposes encourages the antisocial attitude (asozialitat) of the sick undermines the desire for recovery and endangers health.

Against these evils the insurance system aims to protect itself by compelling the physician to act as a sort of detective and by a system of restrictions and supervisions. The patient knows all about these restrictions, and if he does not receive the latest highly advertised and expensive drugs or the most

The insurance administrators in all countries try to control admission to insurance practice. When this practice dominates the field, as it does in most European countries today, this practically places the insurance societies in the position of licensing bodies. The societies next seek to influence education so as to prepare the physician for the sort of medical practice that the insurance society thinks necessary.

Because of the character of insurance practice, observers hold that there is a tendency to neglect graduate work. Concerning this point Kurt Finkenrath says ¹⁷

I made a statistical study in 1919 to determine from what sections of Berlin the majority of the physicians came to attend the graduate courses of the Central Committee of the Kaiserin Friedrich Haus. This made clear the fact that three fourths of all participants came from the West and Southwest and that all other sections of Greater Berlin furnished only one fourth. From this division the conclusion was drawn that the physicians who had an interest in further education were overwhelmingly those who still had some share of private practice while the great mass of the insurance physicians were far from desiring any further education.

Chart 1—Morbidity in German local insurance societies (ortskrankenkassen). Solid line is smoothed curve of actual morbidity rates as measured by certified cases of incapacity for work; the trend line is dotted.

sensational and fashionable treatment with costly x-ray or other machines, he is convinced that this is not because these treatments are unnecessary but because the society's orders for economy prevent their use in his case.

The most severe criticism of medical service under insurance is not based on the occasional examples of overworked practitioners, with resulting hasty careless diagnosis and treatment but rather on the atmosphere of suspicion and antagonism, which destroys the very foundations of good service. Payment into a general fund over which the insured has no control, and from which he can get back his money, to which, rightly or wrongly, he believes he is entitled, only by being sick, creates the conditions described.

THE PHYSICIAN IN SICKNESS INSURANCE

The same story is repeated in the evolution of nearly every insurance system. In the beginning the physicians cooperated and often contributed their services. When the physicians resisted the efforts to debase medical service and the medical profession, the result was a continuous battle between the physician and the insurance administrators.

The first effect of insurance is to pay the physician for much of the work that he did before for charity and thereby to increase many medical incomes. Later when the medical profession has become dependent on the insurance society, work is increased and income reduced.

This conflict between the physician and the society has led to the formation on both sides of international organizations. The International Association of Physicians after a most exhaustive research drew up resolutions on the attitude of the medical profession to sickness insurance. It must be remembered that this organization did not have before it the question of whether insurance should be introduced but was faced with an accepted fact in the shape of an existing system. The association declared its general approval of the principles of social insurance and then set forth at great length the principles which it felt must be maintained in the interest of good medical service.

The medical service must remain autonomous as to all questions concerning the practice of medicine.

Insurance should be 'applied only to those persons who are incapable of meeting the necessary costs of medical care in case of sickness from their own resources.'

The insured should always share in the cost of medical care and drugs.

There should be complete free choice of physician permitting all licensed physicians who accept insurance regulations to share in the care of the sick.

Professional secrecy should be maintained.

¹⁷ Finkenrath, Kurt. *Krankenhilfe und Gesundheitsfürsorge durch die Aerzteschaft*, pp. 119-121. The attitude of the insurance societies is presented by Franz Korrus, secretary, German Insurance Societies of Czechoslovakia. *Compte rendu*, p. 75.

There should be no restriction of the right to prescribe, although the medical organizations should always 'seek to suppress all expensive and superfluous medication'

Payments should not be by a fixed sum per person or by salary (The British Medical Association objected to this rule and stated that it preferred the system now existing in England)

Sickness insurance is one phase of the effort of industrial civilization to force a recalcitrant profession into industrial patterns. Such insurance means that a professional service is to be supplied under compulsion. The medical profession maintains that the very character of the service is such that it will be destroyed by such compulsion.

Advocates of sickness insurance usually deny any such attack on professional status, yet the official statement of the International Conference of National Unions of Mutual Societies and Sickness Insurance Societies, which includes the carriers of sickness insurance in all the principal European nations, has declared that only through mechanization and contract

German and English observers question very much whether the \$300,000,000 in the former country and the \$160,000,000 in the latter spent annually for insurance would not produce far better effects on the public health if expended in other directions.²⁰

It is difficult to say clearly to what extent any system of sickness insurance is satisfactory to the people involved. The political power of the insurance societies makes any movement for the abolition of an existing system practically impossible. The conditions at the time of the origin of the English system were infinitely worse in regard to medical care than now prevails in the United States.

The Majority Report of the Committee on the Costs of Medical Care, which recommends sickness insurance, says:²¹ "It is probably true that in the United States, except for some rural areas, a much larger amount of medical service is available, and is actually obtained, even by low-wage-earners, than was the case in any European country during the period when

Chart 2—Morbidity and business conditions 1890-1913. Solid line shows depressions and prosperity in reverse with crises at high and prosperity at low points. Lower open line with circles shows sickness record of Pomeranian local societies (ortskrankenkassen). Upper line with solid dots of industrial societies (betriebskrankenkassen).

employment of the physician can insurance be successfully conducted.¹⁸

This position has been officially endorsed by the International Labor Office.¹⁹

The majority report of the Committee on the Costs of Medical Care and the writings in support of sickness insurance schemes show the same desire to develop the 'large exploitation' of medical practice through groups, medical centers, clinics and insurance, and the same tendency to place the control of such institutions under lay management. The whole history of industrial and contract practice, both within and without the system of workmen's compensation, repeats the story. Everywhere there is the same effort to destroy professional status and personal contacts between producers and consumers of professional service, and to substitute the contract relations of a lay employer hiring physicians supplying an impersonal market.

Sickness insurance demands the expenditure of immense sums, which experience has shown produce no reduction in morbidity or mortality rates. On the other hand there is ample proof that the expenditure of similar sums in public health service, sanitation, pure food control, immunization and various other directions will improve the public health.

its health insurance system was developing." Under such conditions as prevailed in these European countries, almost any change was an improvement.

The questionnaire of the International Association of Physicians included a query on the extent of satisfaction to the insured and the physician. The replies are given in the last two columns of table 3. Of the four nations that reported general satisfaction, two Bulgaria and Denmark have so completely transformed their system since these replies were given as to raise serious question as to present satisfaction, and in Holland little more than a workmen's compensation law exists. Great Britain remains the only nation expressing fairly general satisfaction, yet parliamentary investigations and reports of royal commissions and other bodies show that a large percentage of those affected in Great Britain question strongly whether the same amount of money might not have been spent with greater benefit to the health in other ways.

A movement that has recently gained great strength in Germany and is of considerable importance in other countries would seem to indicate that where systems of sickness insurance

are old enough to have worked out their full results there is a widespread doubt as to whether the attempt to distribute the whole burden of medical care and relief during sickness should not be abandoned in favor of a return to individual responsibility for a portion at least of that burden

The Swedish, Norwegian, French and Chilean systems have always required the insured to bear a portion of the burden when the service is given. In Denmark, Switzerland and Luxemburg only a part of the cost of drugs is paid by the insurance system. It is noteworthy that complaints of excessive practice and overmedication are seldom heard in these countries and that they have not shown any such alarming increase in "morbidity" as has characterized other systems.

In Germany, and also in some other countries with long experience with compulsory insurance, there is a strong movement, especially among physicians (although by no means confined to them) in favor of some sort of compulsory system of saving as a substitute for insurance as at present operated.²²

There is considerable variation in the details of the proposals of these various writers, but all involve the principle of segregation of all or part of the contributions of the insured and of returning a certain portion at death or at the age when an old age pension is granted or else to offer a cash reward or suspension of contributions to those who have not asked the aid of the fund for a certain period. A similar plan has been vigorously urged by P. Specklin, a physician with a long pre-war experience under the Germany system at Mulhouse.²³

TABLE 4—Infant Mortality in Prussia

	1913	1920	1926	1927	1928	1929
Among the wealthy	65	41	41	36	34	34
In the middle class	89	65	64	64	59	66
In the working class, excluding those occupations in which there are a large number of illegitimate children	141	104	101	97	94	103
Working class including occupations with many illegitimate children	214	166	149	143	125	135

The fact that the actuarial basis of the English system has proved to be wholly unreliable and that no method has been found of calculating the tremendous increase in morbidity due to economic and psychologic reasons throws doubt on the question as to whether any of the existing or immediately proposed forms of sickness insurance offer any satisfactory solution of the distribution of medical care. One thing is clearly evident: the degree of satisfaction of insured and physician in practically every country depends on the extent to which medical professions have been able to defeat the schemes of lay administrators. England, France and the Scandinavian countries are the nations where professional control is most complete and where the sort of proposals that are urged by lay forces in this country as the basis of sickness insurance have had least development. They are also the ones where morbidity has shown the slowest rate of increase where physicians and insured express the greatest satisfaction and where even the societies are in the best financial condition.

22 Hartz G. Neue Wege in der Sozialpolitik 1929. Muller Arthur. Zwangssparsystem statt Sozialversicherung 1929. Lick Erwin. Soziale Versicherungen und Volksgesundheit 1929. Zeisler August. Im Kampf gegen Vergewaltigung durch den Staat 1931. Hartz Gustav. Eigentum oder Rente 1930. Baumeier Waldemar. Die Krankenversicherung, Jetzt ein Fluch umgestaltet ein Segen für das Volk 1930. The intentions of the Nazi government were outlined by Hadenkamp in the Aerztliche Mitteilungen March 11 1933, pp 223 225 where he says concerning this phase of the subject. The exact form that this fundamental reform will take cannot be stated today. A certain role will be played by the idea of directing insurance into a compulsory savings system. As is well known this idea has for a long time been active in the public mind and has been discussed by the medical profession. In medical circles it has been differently estimated some have welcomed it strongly. The national socialist movement has declared itself for the development of the idea of saving but has coupled this with the proposal for fundamental changes. State Secretary Dr Krohn in an interview with the representative of a great daily paper has declared that he saw possibilities in a sound combination of insurance and savings. He thought—and that is important for us—to be sure only of the cash insurance not of sickness insurance.

Association News

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast to coast network each Monday afternoon from 4 to 4 15 Central daylight saving time (4 o'clock Eastern standard time 3 o'clock Central standard time, 2 o'clock Mountain standard time, 1 o'clock Pacific standard time)

The next three broadcasts will be as follows

- May 14 Pursuit of Longevity Morris Fishbein M D
- May 21 Disease by Air W W Bauer M D
- May 28 The Family Medicine Chest Morris Fishbein M D

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time. The next three broadcasts will be as follows

- May 17 Mischievous Misconceptions, W W Bauer, M D
- May 24 Character of a Quack Morris Fishbein M D
- May 31 Health Slogans W W Bauer, M D

THE CLEVELAND SESSION

Radio Addresses to Be Broadcast During the Week

A simple program of a practical nature has been arranged for broadcasting during the week of the convention, over Stations WTAM, WHK and WGAR

RADIO STATION WTAM (NATIONAL BROADCASTING COMPANY)

Talks on the following subjects will be made late in the afternoon

- Monday June 11 Common Cold Wilson G Smilie M D (network)
- Tuesday June 12 New Diabetics for Old Priscilla White M D
- Wednesday June 13 Your Doctor W L Biering M D
- Thursday June 14 Convention Highlights, Morris Fishbein M D

RADIO STATION WHK (COLUMBIA BROADCASTING SYSTEM)

Talks on the following subjects likewise will be made late in the afternoon

- Monday June 11 Health Examinations Wingate Johnson M D
- Tuesday June 12 Family Doctor N B Van Etten M D (network)
- Wednesday June 13 Cancer Is Curable Max Cutler M D
- Thursday June 14 Medicine Marches Forward Morris Fishbein M D (network)

RADIO STATION WGAR

On Station WGAR the following subjects will be broadcast

- Monday June 11 Appendicitis John O Bower M D
- Tuesday June 12 Simple Cheap Happy Thurman B Rice M D
- Wednesday June 13 Blood Building Foods James S McLester M D
- Thursday June 14 Relieving Hay Fever and Asthma G W Waldbott, M D

Golf Tournament for Women Physicians

Women physicians who desire to enter the annual golf tournament at the Cleveland session are requested to send their names to Dr Harriet Doane, Pulaski, N Y, or to Dr Helena Ratterman, 126 East Auburn Avenue, Cincinnati, Ohio. For news of the golf tournament for men see page 1579

Additional Annual Dinners During the Cleveland Session

The Alumni dinner of Rush Medical College of the University of Chicago will be held at the Hotel Statler Wednesday June 13, at 7 p m, \$1 50 per plate. For reservations and other information please inquire of Dr Austin A Hayden at the Hotel Statler

The Alpha Omega Alpha annual dinner will be held Thursday, June 14, at the Hotel Cleveland at 6 30 p m, \$2 per plate. For reservations and other information please inquire of Dr Josiah Moore at the Hotel Cleveland

For other reunions and dinners during the Cleveland session see pages 1578 and 1579 in this issue of THE JOURNAL

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Stop Shipment of Parrots—Newspapers reported, April 3, that the certification of psittacine birds for shipment had been halted by Dr. Jay D. Dunshee, Sacramento, director of public health of the state board of health, pending further investigation of reported cases of psittacosis. The order affects birds shipped both within and to points outside the state. Fourteen of the sixty-seven cases of psittacosis reported in the state since Dec. 1, 1931 have been fatal. It was stated that other states have reported 106 cases, with twenty-two fatalities.

Southern California Meeting—The nineteenth semiannual meeting of the Southern California Medical Association was held in Santa Barbara April 6-7, under the presidency of Dr. Henry Douglas Eaton, Los Angeles. The following physicians participated in the program:

Will L. Miles, Los Angeles: Split Skin Grafts.
Francis B. Settle, Long Beach: Phytobezoar Associated with Gastric Ulcer.
William M. Moffat, Santa Barbara: Follutein in the Treatment of Selected Cases of Headache.
Percival A. Gray, Jr., Santa Barbara: Insulin in the Treatment of Food Allergy.
Samuel Hirschfeld, Los Angeles: Dyscolulation.
Noel F. Shambaugh, Long Beach: Thorium Dioxide as a Diagnostic Aid.
Rexwald Brown, Santa Barbara: Collectivism in Medicine—A Movement Which Should Be Promoted.
Rea Smith, Los Angeles: A Study of Abdominal Adhesions.
Charles C. Coghlan, Los Angeles: Red Hair and Its Relation to Allergy.
Chalmers Hiram Weaver, Los Angeles: Cancer of the Cervix.

Dr. Cyrus Sturgis, professor of internal medicine, University of Michigan School of Medicine, Ann Arbor, spoke on 'Treatment of Anemias' and 'Observations Concerning the Etiology of Agranulocytosis.'

Society News—Dr. John D. Camp, Rochester, Minn., addressed the San Francisco County Medical Society, May 8, on 'Roentgenologic Findings in Hyperparathyroidism.'—A program sponsored by the San Mateo County Medical Society was presented at the Veterans' Administration Facility, Palo Alto, April 19, with Dr. Arthur L. Bloomfield, San Francisco, as speaker, on 'Present Status of Focal Infection in Relation to the Practice of Medicine.'—Dr. Ralph Kaysen, San Diego, discussed Boehler methods before the San Diego County Medical Society, April 10.—Dr. Russell L. Cecil, New York, addressed the San Diego Academy of Medicine, April 27, on 'Modern Treatment of Rheumatoid Arthritis.'—Harold F. Hawkins, D.D.S., addressed the Hollywood Academy of Medicine, April 19, on 'Mineral Metabolism as Related to Medicine' and Dr. Rea Proctor McGee, 'Inter-Relationship of Medicine and Dentistry.'—Speakers before the Los Angeles Surgical Society, April 13, included Drs. Lucius W. Johnson and Joseph L. Schwartz, captain and lieutenant commander, respectively, U. S. Navy, on 'Head Injuries' and 'Practice of Medicine in American Samoa.'—At a meeting of the San Francisco Pathological Society, March 29, Drs. Frederick A. Proescher and Adelbert M. Moody, among others, discussed 'Forensic Methods for Examination of Blood.'—Dr. Albert H. Rowc, Oakland, addressed the San Joaquin County Medical Society, April 5, on 'Problems of Allergy in Medical Practice.'—Dr. Charles A. Duker, Oakland, discussed the Alameda County health insurance plan before the Solano County Medical Society, April 10.

COLORADO

Society News—A symposium on cancer of the breast was presented before a joint meeting of the Boulder and Larimer county medical societies, April 4, by Drs. William W. Haggart, Wilfred S. Dennis and Frederick E. Diemer.—At a meeting of the Medical Society of the City and County of Denver, April 17, Reuben G. Gustavson, Ph.D., and Fred E. D'Amour, Ph.D., discussed 'Recent Studies in the Human Sex Cycle and Recent Hormone Studies During Pregnancy,' respectively. The society was addressed April 3 by Drs. Theodore E. Boyer on 'Orogenic General Sepsis,' Walter W. King on 'Neoplasm of the Breast,' and Alexander W. Freshman on 'Breast Surgery' (motion picture).

Spring Clinics at Pueblo—Three days were given over to the spring clinics of the Pueblo County Medical Society, April 18-20, under the auspices of the Colorado State Medical Society. The subjects treated included:

Electrosurgical Resection in Carcinoma of the Breast, Dr. William Senger.
Tonsillectomy in Modified Suspension Position, Dr. Clarence E. Earnest.
Obstetrical Practice in a Rural Community, Dr. George E. Van Der Schouw.
Puerperal Eclampsia: Cause, Prevention and Treatment, Dr. William F. Singer.
Problems in Infant Feeding, Dr. John D. Geissinger.
Treatment of Squint, Dr. Guy H. Hopkins.
Chronic Suppurative Otitis Media—Its Treatment by Radical Mastoid Operation, Dr. James J. Pattee.
Blood Dyscrasias, Dr. Frederick M. Heller.
Trichomonas Vaginalis: Its Etiologic Relationship to Leukorrhea, Dr. John B. Farley.
Problems in Medicolegal Practice, Mr. Benjamin F. Koperlik.

DISTRICT OF COLUMBIA

Personal—Dr. Benjamin P. Watson, New York, gave one of the lectures in the Smith-Reed-Russell series at George Washington University School of Medicine, March 27, on 'Present-Day Conceptions of Puerperal Sepsis.'—*Science* reports the death, February 7, of Felix Neumann, aged 76, until recently assistant librarian at the Army Medical Library.

Health at Washington—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended April 28, indicate that the highest mortality rate (18.4) appears for Washington, and for the group of cities as a whole, 12. The mortality rate for Washington for the corresponding period last year was 15.5, and for the group of cities 11.3. The annual rate for eighty-six cities for the seventeen weeks of 1934 was 12.6 as against a rate of 12 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Medical Bills in Congress—H. R. 9395, introduced by Representative Weideman, Michigan, proposes to provide compensation for disability or death resulting from injury to employees in certain employments in the District of Columbia. The bill would authorize an injured employee to select a physician to treat his injury, the reasonable cost of such treatment to be paid by the insurer, subject to the approval of the Deputy Commissioner. The bill would further authorize the Deputy Commissioner to order a change in the physician, surgeon, hospital or other requirement if, in his opinion, reasonable ground exists for believing that such a change is necessary to safeguard the life, health or recovery of the employee. All fees and other charges for treatment or service are to be limited 'to such charges as prevail in the same community for similar treatment of injured persons of like standards of living' and are to be subject to regulation by the Deputy Commissioner.

Course in Female Endocrinology—The George Washington University School of Medicine opened a course in female endocrinology, May 4, to continue until May 28. The following lectures comprise the course:

May 4, A Historical Review of the Female Sex Endocrinology: Physiology of the Sex Glands, Dr. Jacob Kotz, clinical professor of obstetrics and gynecology.
May 7, Chemistry of the Female Sex Hormones, Vincent De Vigneaud, Ph.D., professor of biochemistry.
May 11, Clinical Hormone Tests: Technic, Indications and Interpretations of Results, Dr. Elizabeth Parker, research associate in endocrinology.
May 14, Functional Bleeding: Role of the Endocrines in the Menopause, Dr. Howard I. Kane, professor of obstetrics and gynecology.
May 18, Dysmenorrhea: Etiology and Treatment, Scanty and Irregular Menses, Amenorrhea, Dr. Kotz.
May 21, Premature Termination of Pregnancy Due to Endocrine Disturbances, Dr. Kane.
May 25, The Endocrines in Obesity and the Neurotic Women with Disturbed Endocrine Function, Dr. Kotz.
May 28, Frigidity: Oversexed Women and Functional Sterility, Dr. Kotz.

ILLINOIS

Society News—A symposium on peptic ulcer was presented before the Sangamon County Medical Society, April 5, by Drs. Charles L. Patton, Frank N. Evans, Richard F. Herndon, Thomas D. Masters, Lawrence M. Hilt and David J. Lewis, Springfield.—Speakers before the Bureau County Medical Society in Princeton, April 10, were Drs. Philip H. Kreuscher and Ernest E. Irons, both of Chicago, on backache and causes and treatment of chronic arthritis, respectively.—Dr. Meyer Solomon, Chicago, discussed nervous breakdowns before the Will-Grundy County Medical Society, April 11.—At a meeting of the Iroquois County Medical Society, April

12, Dr Philip Rosenblum, Chicago, spoke on "Convulsions in Children"—The Fulton County Medical Society was addressed in Canton, April 18, by Dr James P Simonds, Chicago, on nephritis—At a meeting of the Kane County Medical Society in Aurora, April 11, Dr Irving F Stein, Chicago discussed "The Use of Obstetric Forceps"—Dr Herbert N Rafferty, Robinson, among others, addressed the Crawford County Medical Society, April 18, on "Multiple Fractures and Traumatic Epilepsy"—The Peoria City Medical Society was addressed May 1, by Dr Chauncey C Maher, Chicago, on "Treatment of Cardiac Edema" The society was addressed, April 17, by members of the state health department Dr Frank J Jirka amebiasis, Howard J Shagline, Ph D, the doctor and the diagnostic laboratory, and Dr Robert H Woodruff, the doctor and vital statistics

Chicago

Capps Prize to Dr Kistler—The Institute of Medicine of Chicago has awarded the Joseph A Capps Prize for medical research for 1933 to Dr Gene H Kistler, University Ala, for his paper on "Sequences of Experimental Infarction of the Femur in Rabbits" Dr Kistler graduated from Rush Medical College in 1931 The prize of \$500 is awarded annually for meritorious medical research by a graduate of a Chicago medical school, completed within two years after graduation

Society News—Dr John T Murphy, Toledo, addressed the Chicago Roentgen Society, May 10, on "Bone Tumors"—The Chicago Tuberculosis Society was addressed, May 10 among others, by Dr John B O'Donoghue on "Surgery of Pulmonary Tuberculosis"—Speakers before the Chicago Pathological Society, May 14, will include Dr Emil T Hoverson, Kankakee, Ill, on "Sedimentation Rate of Erythrocytes An Explanation for Normal Daily Variations"—The Chicago Academy of Criminology was addressed, May 10, by Benjamin C Bachrach, public defender of Cook County on "Criminal Code and Indeterminate Sentence," and Prof Harrison Dobbs of the University of Chicago, "The State's Responsibility in the Correctional Education of Children"

INDIANA

District Meeting—The Ninth District Medical Society will hold its annual meeting at the Country Club Frankfort, May 17, when Mayor C E Crawford will give the address of welcome Speakers will include Drs Ralph G Carothers, Cincinnati, on "Treatment of Compound Fractures", Edwin N Kime, Indianapolis, "Prognosis in Cancer," and William F McBride, Dayton, "The Country Doctor—Forty Years of It" Dr Charles P Emerson, Indianapolis, will give the banquet address on "Oriental Medicine" A golf tournament will be a feature of the session

Society News—Dr Maurice Joseph Barry, among others, will address the Indianapolis Medical Society, May 15 on "Heredity in Anemia" Dr Dean Lewis, Baltimore, President American Medical Association, will discuss "Tumors of the Breast" before the society, May 22, meeting jointly with the graduate group of the Indiana University Medical Center—Dr Richard B Stout, Elkhart, spoke before the North-eastern Indiana Academy of Medicine at Kendallville, April 26, on "Spinal Anesthesia—Volume Control Technic"—Dr Julius R Yung, Terre Haute, discussed exophthalmic goiter before the Gibson County Medical Society in Princeton, April 9—At a meeting of the LaPorte County Medical Society in Michigan City, April 12, Dr Victor D Lespinasse, Chicago, spoke on "The Childless Couple—Cause and Cure"—Dr Percy E McCown, Indianapolis, addressed the Clinton County Medical Society in Frankfort, April 5, on "Transurethral Removal of Bladder Neck Obstructions"—Dr Harold Dale Pyle, South Bend, addressed the St Joseph County Medical Society, April 3, on "Nutritional Diseases of Infants and Children"

IOWA

Society News—The Linn County Medical Society was addressed, May 3, by Dr Fred L Adair, Chicago, on "Maternal Mortality and Morbidity"—Speakers before the Des Moines Academy of Medicine and Polk County Medical Society, April 24, included Drs Helen Johnston and Edward J Harnagel on trichomonas vaginalis vaginitis and jaundice, respectively

Annual Renewal Fees Due Before June 1—All licenses to practice medicine and surgery in Iowa expire annually on June 30 To renew such a license a licensee must make a written application to the state department of health before June 1, enclosing the renewal fee of \$1 If a license expires

by reason of the licensee's failure to renew it, it can be reinstated without reexamination only on the recommendation of the board of health and the payment of the overdue fees

Annual Birthday Banquet—In celebration of his sixty seventh birthday, Dr William A Rohlf, Waverly, recently held his annual birthday dinner and clinic More than 100 professional friends of Dr Rohlf attended With Dr Jay F Auner, Des Moines, as toastmaster, speakers included Drs Charles B Taylor, president of the state medical society, Robert L Parker, Des Moines, secretary of the state society, Leonard A West, Des Moines, and Charles H Graemling, Waverly A huge birthday cake bearing sixty-seven candles was presented to Dr Rohlf by Dr and Mrs John McDannell, Nasliua A surgical clinic was held in the morning and a medical clinic in the afternoon Speakers included Drs Harold C Haben and Virgil S Counsellor, Rochester, Minn, on internal medicine, Howard L Beye, Iowa City, surgical conditions of the chest, and Fred M Smith, Iowa City, thyroid disorders About 142 physicians attended the clinics Dr Rohlf a past president of the Iowa State Medical Society, has been holding this birthday clinic celebration for several years

KENTUCKY

Health Report for 1933—Preliminary statistics issued by the state department of health show that the death rate in Kentucky for 1933 was 107 per thousand of population, the same as the preliminary rate in 1932, later raised to 112 Mortality among infants less than 1 year old fell from 685 in 1932 to 595 in 1933 Pneumonia, whooping cough, scarlet fever, measles, influenza and the diarrheas showed decreases, but diphtheria and typhoid increased slightly The tuberculosis rate was the same as the preceding year, 858

Society News—Dr Chauncey W Dowden, Louisville, addressed the Franklin County Medical Society, Frankfort, March 8, on secondary anemia—Drs Rettig A Griswold and Robertson O Joplin presented a paper on "Fracture of the Lower Extremity" before the Jefferson County Medical Society, Louisville, April 2—Drs Seale Harris, Birmingham, and Seale Harris Jr, Nashville, Tenn, addressed the Christian County Medical Society, Hopkinsville, March 20, on "Hypertension and Its Relation to Epilepsy and Epileptiform Convulsions" and "Treatment of Syphilis," respectively

LOUISIANA

Dr Jackson Lectures—Dr Chevalier Jackson, professor of bronchoscopy and esophagoscopy, Temple University School of Medicine, Philadelphia, gave a series of lectures at Louisiana State University Medical Center, New Orleans, April 16-19 His subjects included "Diagnosis of Foreign Bodies in the Air and Food Passages," with motion picture demonstration of the mechanism of valvular obstruction, "Diseases of the Esophagus," with demonstration of esophagoscopy for diagnosis, and "Bronchoscopy as an Aid in the Diagnosis and Treatment of Pulmonary Diseases" Dr Jackson is visiting professor at the medical center

MAINE

State Medical Meeting at Bangor, May 27-29—The eighty-second annual meeting of the Maine Medical Association will be held at Bangor, May 27-29, with headquarters at the Bangor House, and under the presidency of Dr Warren E Kershner, Bath Dr Dean Lewis, Baltimore, President of the American Medical Association, will speak Tuesday, on "Differential Diagnosis of Breast Tumors" Reviewing the year's progress in medicine, speakers will be Drs Eugene H Drake, Portland, and John O Piper, Waterville, in ophthalmology, Erastus E Holt Jr, Sylvester J Beach, Portland, and Howard F Hill, Waterville, in surgery, Edward H Risley, Waterville, and Frank H Jackson, Houlton, otolaryngology, Henry P Johnson and George O Cummings, Portland and pediatrics, Thomas A Foster, Portland Physicians on the scientific program will include

Magnus F Ridlon Bangor Ectopic Pregnancy
Alfred Mitchell Jr Portland Structures of the Urethra
Harold D Ross Sanford Abdominal Complications in Obstetrics
Oscar R Johnson Portland Skin Manifestations in General Disease
Frederick T Hill Waterville, Acute Throat Conditions
Sullivan L Andrews Lewiston Significance of Eye Symptoms in Head Injuries
George E Young, Skowhegan Thoracic Surgery Results of Collapse Therapy in State Sanatoriums
William A Ellingwood Rockland Focal Infections in Ear, Nose and Throat and Their Relation to Systemic Disease
Raymond V A Bliss Bluehill Diseases of the Arteries

At the annual banquet, Tuesday evening, addresses will be made by Dr Kershner and Dr Lewis

MARYLAND

Tuberculosis Clinics for Negroes—As a special feature for the observance of National Negro Health Week, the Maryland Tuberculosis Association conducted four special tuberculosis clinics for Negroes in the counties of the state

April 3, Fairmont Heights Prince George's County
April 5, Prince Frederick Calvert County
April 6, Bowie Prince George's County
April 6, St. Michaels, Talbot County

Dr Warthen Named Assistant Health Commissioner—Dr William H. F. Warthen, for ten years director of the bureau of child welfare, has been appointed assistant commissioner of health of the Baltimore City Health Department, succeeding the late Dr John Frederick Hempel. Dr Humphrey Warren Buckler has been acting temporarily in this position pending a permanent appointment. Dr Warthen, 37 years old, is a graduate of Johns Hopkins University School of Medicine.

Medical Advisory Board—Appointment of a medical advisory board for the Baltimore City Hospitals, with Dr George Walker as chairman, was announced, April 6. Other members of the board include Drs Alan M. Chesney, dean, Johns Hopkins University School of Medicine, James M. H. Rowland, dean, University of Maryland School of Medicine, Huntington Williams, health commissioner, Thomas R. Boggs, Arthur M. Shipley and Charles C. Hablston, and Mr Parker J. McMillin, superintendent of the city hospitals.

MASSACHUSETTS

Precipitation Test to Be Used by State Department—The Massachusetts Department of Public Health, as the result of several years of comparative study of various types of serologic tests for syphilis and in view of the majority opinion of both local syphilologists and serologists in many of the states and laboratories, is now using a precipitation test for official routine purposes. Use of the new test was begun, April 2. According to Dr Henry D. Chadwick, commissioner of public health, the precipitation test was developed by Dr William A. Hinton, chief of the state serologic laboratory.

Society News—Speakers before the New England Pediatric Society in Boston, March 23, included Drs James L. Gamble and Stewart H. Clifford on "Present Knowledge of the Food Substances" and "Factors Influencing the Viability of Premature Infants," respectively. Drs J. Herbert Waite and William P. Beetham presented a paper on "Ocular Complications in Diabetes" before the New England Ophthalmological Society, April 17. At a meeting of the New England Roentgen Ray Society in Boston, April 20, speakers included Drs Harry F. Friedman and Abram Louis Hermanson on "Protected Irradiation in Carcinoma of the Larynx" and "Roentgenologic Exploration of the Biliary Ducts with Iodized Oil," respectively. Dr Edwin A. Locke discussed "Hypertension, Its Cause and Treatment" before the Malden Medical Society in Malden, April 17. Dr Albert A. Epstein, New York, spoke before the William Harvey Society in Boston, April 13, on "Diseases of the Kidney in General Practice."

MICHIGAN

Dr Campbell Named Mayor—Dr James B. Campbell took office as mayor of Big Rapids, April 9, he is the fourth physician to hold the office in the history of the city. He is president of the Mecosta County Medical Society and, for the past four years, has been city commissioner. Dr Campbell has been practicing in Mecosta County since 1900.

Dinner to Dr Chene—The staff of Providence Hospital, Detroit, gave a dinner at the Detroit Athletic Club, May 3, in honor of Dr George Charles Chene, who has been connected with the institution for twenty years and secretary of the staff for the last fifteen years. He has held various teaching positions in the departments of gynecology and roentgenology at Detroit College of Medicine and Surgery since 1908.

MISSOURI

Society News—The St. Louis County Medical Society is now publishing a bimonthly bulletin. The initial copy was dated February 28. Speakers before the society, April 11, included Drs Franz J. Arzt on "Syphilis in Pregnancy" and John Gray Jones "Management of Posterior Presentation." Dr Ernest Kip Robinson, Kansas City, addressed the Lafayette County Medical Society, March 24, on "Newer Methods in Cancer Treatment." Dr Harvey J. Howard presented the "Adventures of an American Physician in China" before the St. Louis Medical Society, April 10. Members of the St. Louis Trudeau Club presented a symposium on the

prognosis of pulmonary tuberculosis before the society, April 3. Dr Sidney I. Schwab spoke before the St. Louis Neuro-psychiatric Society, April 23, on "The Utilization of Freudian Concepts in Neurology and Psychiatry." Dr Otto Jason Dixon, Kansas City, addressed the Golden Belt Medical Society at Junction, April 5, on "Advantage of Conservative Treatment in Acute Mastoid Disease" and the Panhandle District Medical Society at Amarillo, Texas, April 10, on "A New Method for Surgical Treatment of Sigmoid Sinus Thrombosis with the Use of Viable Muscle Implant."

NEW YORK

Society News—Dr Edward C. Reifstein, Syracuse, addressed the Utica Academy of Medicine, recently, on cardiac pain. Drs John P. Peters, New Haven, Conn., and Neil C. Stevens, Glen Cove, addressed the Medical Society of the County of Nassau, Mineola, March 27, on "Nature and Treatment of Diabetes" and "Auscultation of the Abdomen as a Method of Diagnosis," respectively. Dr Frederick S. Wetherell, Syracuse, addressed the Broome County Medical Society, Binghamton, March 6, on "Sympathetic Nerve Surgery—A Discussion of Its Progress and Rationale." Dr Emanuel D. Friedman, New York, addressed the Chemung County Medical Society, Hornell, and the Steuben County Medical Society, Elmira, April 19, on epidemic encephalitis.

New York City

Personal—Michael Heidelberger, Ph.D., associate professor of biologic chemistry at Columbia University and research chemist to Presbyterian Hospital, has recently been awarded a grant by the Guggenheim Foundation for research on the molecular weight of thyroglobulin at Uppsala University, Sweden. Donald D. Van Slyke, Sc.D., research chemist to the hospital of the Rockefeller Institute for Medical Research, was guest of honor at a dinner, March 29, in honor of his twentieth anniversary in that position.

Society News—At a meeting of the Medical Society of the County of Queens, April 24, Dr Thomas T. Mackie discussed amebiasis and Dr Charles H. Goodrich discussed medical economics. Dr Thomas Drysdale Buchanan delivered a Friday afternoon lecture before the society, April 6, on recent advances in anesthesia. Dr Fred Wise will address the American Stomatological Association, May 15, on "Buccal and Labial Lesions of Interest to Dentist and General Practitioner." Dr Carroll Fox, medical director, U. S. Quarantine Station, Rosebank, L. I., addressed the Public Health Officers Association, April 18, at the headquarters of the city health department, on "Quarantinable Maritime Diseases and Their Method of Spread." At the meeting of the International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists, March 16, a symposium on "Birth and Sex Abnormalities" was presented by Drs Irving W. Potter, Buffalo, Samuel R. Meaker, Boston, James A. Harrar and Ira S. Wile. A testimonial dinner was given to Dr Jacob M. Gershberg, president and founder of the society, April 25, at the Hotel Astor, by the board of directors.

District Health Administration—Plans are going forward for the establishment of health districts to carry out localized health service, in accordance with the results of experimentation that has been carried on for several years in the Bellevue-Yorkville district. Three years ago the Central Harlem Health Center was established with its activities officially related to the central health department and with the cooperation of various official and voluntary agencies. Under the new administration, funds have now become available for the continuation of the plan under the direction of the department of health. A new bureau of district health administration has been created with Dr Margaret Shepard Witter Barnard as temporary director, pending civil service examination. Central Harlem has been made the first official district and Dr Arthur I. Blau, district health officer. Other districts will be chosen shortly. The Coordinating Council of the Five County Medical Societies in a report issued in 1931 approved the establishment of these centers and has taken an active part in the preliminary planning. A technical advisory committee to the commissioner of health and the bureau has been appointed as follows: Drs James Alexander Miller, chairman, George Bachr, Hugh Chaplin, Charles Gordon Heyd and Edward L. Keves, Mr Bailey B. Burritt, Mr Homer Folks, William F. Walker, Dr P. H. and Katherine Tucker, R. N.

Elves in Jail—May Be Deported—Carl R. Elfs who has practiced medicine without a license in various states and under various names, was sentenced to a year in New York County Penitentiary and was also fined \$500 or in default of

payment of the fine to serve 100 days in addition, April 24, after he was found to be practicing without legal authorization as physician to Hart's Island Prison, this time under the name Max R. Schneller. Schneller received a temporary appointment as psychiatrist to the prison in March, when the department of correction was making drastic changes in its medical staff. After being pressed for his license for some time, Schneller applied to the state board of medical examiners in the name of Dr. Max Schneider, a reputable physician, and as a result of the subsequent investigation was relieved from duty, April 12. Immediately after this he attempted suicide by taking an overdose of a sedative drug. When arraigned in court two days later he pleaded guilty, fainting twice during the hearing. He again collapsed in court when he was sentenced ten days later. The checkered career of Schneller-Elles has been reviewed in *THE JOURNAL* (Sept. 17, 1927, May 3, 1930, p. 1419, and July 11, 1931, p. 111), and the *Federation Bulletin*, published by the Federation of State Medical Boards of the United States, printed in January 1928 a long account of his activities up to that time. Information from the probation department of the New York Court of Special Sessions indicates that an effort will be made to deport him. He claims to be a native of Germany and to have been adopted by a Baron Arthur von Schneller. It was reported that he was employed at Hart's Island at a salary of \$1,450 a year and maintenance.

OHIO

University News—Beginning next September, the school of nursing of Western Reserve University will become a graduate professional school. Applicants for admission must have completed a course leading to the degree of bachelor of arts, science or philosophy. The course may be completed in thirty-three months.—Rev. John F. Berr, formerly registrar of Western Reserve University School of Dentistry, Cleveland, has been appointed registrar of the school of medicine at the university.

Society News—Dr. Marion A. Blankenhorn, Cleveland, addressed the Toledo Academy of Medicine, April 27, on "Deficiency Diseases of Adults." During the morning of that day medical and surgical clinics were held at Toledo Hospital by the staff and in the afternoon Dr. Blankenhorn conducted a clinic.—Dr. Karl D. Figley, Toledo, addressed the Allen County Medical Society, Lima, March 20, on allergy.—Drs. Elmer I. McKesson, Toledo, and Irwin A. Bottenhorn, Columbus, addressed the Marion County Academy of Medicine, Marion, April 3, on "Anesthesia in Medicine and Dentistry" and "Pulp and Pulp Canal Infection," respectively.—The Doctors' Symphony Orchestra of Akron gave a concert before the Stark County Medical Society, Canton, April 12. Dr. Alexander S. McCormick is director of the orchestra.—Speakers before the Columbus Academy of Medicine, March 12, were Drs. Raymond A. Ramsey on goiter, Francis W. Gosnell, metabolism and hypothyroidism and John E. Briggs, inflammation and malignancy.—Dr. John W. Carmack, Indianapolis, addressed the Montgomery County Medical Society, Dayton, April 6, on "Cooperation of the General Physician and the Otolaryngologist in the Treatment of Nasal Sinus Infection."

OKLAHOMA

Society News—Drs. Harry Wilkins and Don H. O'Donoghue, Oklahoma City, addressed the Comanche County Medical Society, Lawton, March 8, on "Neurosurgical Conditions in Children" and "Injuries About the Knee Joint," respectively.—At a meeting of the Southwestern Oklahoma Medical Association, Clinton, March 20, speakers were Drs. Charles W. Stevenson and Charles R. Hartsook, Wichita Falls, Texas, on "Tumors of the Chest" and "Relation of Ophthalmology and Otolaryngology to General Medicine," respectively, and Drs. Walter W. Wells and Willis K. West, Oklahoma City, on "Care of the Breast in Obstetrics" and "Deformities in Children Due to Fractures," respectively.

OREGON

New State Board Officers—At a meeting of the Oregon State Board of Medical Examiners, April 5, the following officers were elected: Drs. Elza D. Johnson, Klamath Falls, president; Joseph F. Wood, Portland, secretary; and Charles C. Newcastle, Portland, treasurer.

Jones Lectures—Dr. John F. Fulton, Sterling professor of physiology, Yale University School of Medicine, New Haven, Conn., gave the tenth annual N. W. Jones Lectures at the University of Oregon Medical School, Portland, recently. His subjects were "Autonomic Representation in the Cerebral Cortex" and "The Functions of the Frontal Lobes."

PENNSYLVANIA

Public Meeting on Cancer—The Cambria County Medical Society presented a program on cancer for the public, May 10, in Johnstown, as part of its campaign for early diagnosis and treatment. Speakers were Drs. Samuel J. Waterworth, Clearfield, Bernard P. Widmann, Philadelphia, and Joseph C. Bloodgood, Baltimore. Members of the Somerset County Medical Society were guests.

Philadelphia

Coroner May Serve Writ on Sheriff—When the sheriff of Philadelphia was made defendant in a lawsuit recently, the question arose as to who could legally serve a writ on him. After a search of old laws it was discovered that the city coroner was empowered to serve such a writ, as under old English law he was the highest officer in the county. It was the first time such a case had occurred in the memory of city officials, it was said.

Society News—The Philadelphia Heart Association held its annual meeting, April 11, with Drs. Charles H. Miner, Wilkes-Barre, and William D. Stroud as speakers. Dr. Edward B. Krumbhaar was reelected president.—Drs. Hermann L. Blumgart, Boston, and Homer M. Swift, New York, addressed the College of Physicians of Philadelphia, May 2, on "Total Ablation of the Normal Thyroid in the Treatment of Patients with Chronic Heart Disease" and "Current Concepts of the Nature of Rheumatic Fever," respectively.—The Society of the Medical Alumni of the University of Pennsylvania will hold its annual reunion, May 19. Dr. Barton C. Hirst is president and Dr. Alex. Heron Davison, secretary.

The Da Costa Oration and Strittmatter Award—Dr. George W. Crile, Cleveland, delivered the fourth annual Da Costa Oration of the Philadelphia County Medical Society, April 18, on the endocrine glands. At the meeting the eleventh annual Strittmatter Award under the auspices of the society was presented to Dr. Philip F. Williams for his services in the field of maternal mortality. Dr. Williams, a graduate of the University of Pennsylvania School of Medicine (1909), is assistant professor of obstetrics at his alma mater and in the Graduate School of Medicine of the university. In 1930 he was chairman of a committee which made an exhaustive study of maternal mortality. The award, established by Dr. Isidor P. Strittmatter in 1923, is a gold medal given to a physician who has rendered meritorious service or made a valuable contribution to the healing art or to one of the fundamental sciences of medicine.

TENNESSEE

State Medical Election—Dr. John O. Mamer, Nashville, was elected president of the Tennessee State Medical Association at the annual meeting in Chattanooga, in April, succeeding Dr. Hiram B. Everett, Memphis. Sectional vice presidents were elected as follows: Drs. William B. Campbell, Cleveland; East Tennessee, James K. P. Blackburn, Pulaski; Middle Tennessee, and Grailey H. Berryhill, Jackson; West Tennessee, Dr. Harrison H. Shoulders, Nashville, was reelected secretary and editor of the state medical journal. Next year's meeting will be held in Nashville.

Society News—Drs. John E. Gordon, Detroit, and Walker L. Rucks, Memphis, addressed the Gibson County Medical Society, Trenton, March 26, on "Management of Infectious Diseases" and "Vomiting in Infancy and Childhood," respectively.—Dr. Henry A. Callaway, Maryville, addressed the Blount County Medical Society, May 3, on "Calcium Deficiency in Pregnancy."—Dr. Thurman D. Kitchin, Wake Forest, N. C., addressed the Sullivan-Johnson Counties Medical Society, Bristol, April 4, on "Relation of Physiology to Medicine."—Dr. William C. Chaney, Memphis, presented a paper on heart disease before the Obion County Medical Society, Union City, March 29.—Drs. George R. Livermo and James W. Bodley, Memphis, addressed the Fayette at Hardeman county medical societies at the Bolivar State Hospital, April 27, on "Urologic Problems of Interest to the General Practitioner" and "Infections of the Hand," respectively.—Dr. Katharine Dodd addressed the Nashville Academy of Medicine, May 1, on "Guanidine as a Complicating Factor in Certain Diseases of Childhood."

TEXAS

Society News—The Harris County Medical Society entertained its members who are more than 70 years old at a dinner at the Houston Club, March 14. Dr. Martin Lee Graves made the address of the evening on contributions of men of mature years.—Drs. Jerrell Bennett and Roy L. Grogan, Fort Worth,

among others, addressed the Tarrant County Medical Society, Fort Worth, March 7, on placenta praevia.—The semiannual meeting of the Northwest Texas District Medical Society was held in Wichita Falls, March 13, among other speakers were Drs Thomas P Frizzell, Knox City, on amebiasis, Robert E Forrester, Moran, industrial examination, George R Enloe, Fort Worth, acute infection of the hand, and Jackson Stewart Cooper, Abilene.—Drs Elliott M Mendenhall and Alfred I Folsom, Dallas, will address the Dallas County Medical Society, May 24, on "Phrenicectomy in the Treatment of Tuberculosis" and "Analysis of 300 Prostatic Resections," respectively.—Dr Edward H Cary, Dallas, among others, addressed a public meeting sponsored by the Texas Hospital Association at its annual session in Temple, in March, on "The Hospital as the People's Friend"—A symposium on cancer of the cervix and uterus was presented before the El Paso County Medical Society, El Paso, March 12, by Drs James Vance, John W Cathcart and Willis W Waite

WASHINGTON

Society News—Dr Charles C Tiffin, Seattle, addressed the Chelan County Medical Society, Wenatchee March 14, on 'Technic of Thyroidectomy'—Dr Herbert E Coe, Seattle gave an address on "Pyloric Stenosis and Intussusception" before the Kitsap County Medical Society, Bremerton, March 13—Drs Roger S Anderson and Albert J Bowles, Seattle, addressed the Walla Walla Valley Medical Society, Walla Walla, March 8, on "Treatment of Fractures of the Head of the Femur and Tibia" and "Hyperparathyroidism," respectively—Drs Richard W Perry and Souren H Tashjian, Seattle, addressed the King County Medical Society, April 2, on "Matters of Interest to the General Practitioner Concerning Farsightedness, Nearsightedness and Squint" and "Treatment of Infections by the Mobilizations of Histocytes," respectively—The North Pacific Society of Internal Medicine held its biennial meeting in Seattle, March 17 Among speakers were Drs John M Blackford and James M Bowers, Seattle, on "Follow-Up Study of Arterial Hypertension and "Treatment of Delayed Pneumonic Resolution with Irradiation," respectively

WEST VIRGINIA

Society News—Dr Robert K Buford Charleston, addressed the Fayette County Medical Society, Oak Hill, March 13 on borderline hyperthyroidism—Dr Roy Benson Miller, Parkersburg, president of the West Virginia State Medical Association, addressed the Tyler-Wetzel Counties Medical Society, March 13, on medical economics—Drs Harlow R Connell Bluefield, and John I Markell, Princeton, presented papers on appendicitis before the Mercer County Medical Society, Princeton, March 15—Drs Edward T W Hall and Aubrey F Lawson, Weston, addressed the Lewis County Medical Society at the Weston State Hospital in February, on "Injection Treatment of Varicose Veins" and "Traumatic Rupture of the Small Intestine Without External Signs," respectively

State Medical Meeting in Huntington—The sixty-seventh annual meeting of the West Virginia State Medical Association will be held in Huntington, May 14-16, with headquarters at the Pritchard Hotel and under the presidency of Dr Roy Benson Miller, Parkersburg Section meetings will be held Monday afternoon May 14, and general scientific assemblies the next two days The West Virginia Heart Association will meet Monday morning Guest speakers will include

Dr Alfred Friedlander Cincinnati Studies in Oscillometry
Dr Paul D White Boston Evolution of Our Knowledge of Heart Disease
Dr Albert E Russell U S Public Health Service Sclerosis and Other Pulmonary Conditions Resulting from Inhalation of Dust
Dr Eli J Browder Brooklyn Traumatic Lesions of the Spinal Cord and Their Treatment
Dr Merrick F McCarthy Cincinnati Surgery of the Lateral Sinus and Internal Jugular Vein
Drs William L Aycock and Charles F McKhann Jr Boston Symposium on Polymyositis
Dr William B Morrison Columbus Ohio Treatment of Benign and Malignant Lesions of the Stomach and Duodenum
Dr Luther C Peter Philadelphia The Problem of the Cross Eyed Child
Dr Russell L Haden Cleveland Chronic Arthritis
Dr Olin West Chicago Secretary American Medical Association Medical Service A Professional Service

The annual oration on surgery will be given by Dr James R Bloss Huntington on 'Obstetric Application of Surgical Progress', the oration on medicine by Dr George R Maxwell Morgantown, on 'Coronary Disease' Entertainment includes a golf tournament at the Gwyn Country Club to be played each day, a smoker Monday evening and a dinner dance Wednesday evening

GENERAL

Medical Bills in Congress—*Bills Introduced* S 3510, introduced by Senator Couzens, Michigan, would authorize the withdrawal of alcohol tax-free "for the use of any clinic operated for charity and not for profit, including use in the compounding of bona fide medicines for treatment outside of such clinics of patients thereof, but not for sale" H R 9405, introduced (by request) by Representative Knutson, Minnesota proposes to revise the laws and regulations relating to pensions and other allowances for veterans and their dependents

Academy of Pediatrics—The fourth annual meeting of the American Academy of Pediatrics will be held in Cleveland, June 11-12 Monday morning and Tuesday afternoon will be devoted to round table discussions led by Drs Thomas B Cooley, Detroit, Herbert E Coe, Seattle, Isaac A Abt, Chicago Borden S Veeder and Hugh McCulloch, St Louis Arthur H Parmelee, Oak Park, Ill, John A Toomey, Cleveland, and Bela Schick, New York At an afternoon session Monday Dr Arvid Wallgren, Gothenburg, Sweden, will give an address and Drs Frederick F Tisdall, Toronto Ont, and Roy G Hoskins, Boston, will speak on "Dental Caries" and "Ductless Glands," respectively

Control of Noise—Technical advances in methods of controlling noise will eventually result in voluntary control of a large part of urban noise, but suitable noise abatement ordinances are essential to achieve results in the near future, in the opinion of a committee of the American Public Health Association recently made public The committee believed that municipal health officials should assume responsibility of the enforcement of such ordinances, since the health aspect is the chief factor in noise abatement It should be handled by a noise abatement commission to coordinate the activities of the various municipal departments concerned and to arouse public interest in noise abatement campaigns, the committee recommended, closing with the suggestion that the study be continued until noise abatement becomes sufficiently standardized to permit a comprehensive final report

Orthopedic Surgeons' Meeting—The American Orthopedic Association will hold its annual meeting in Rochester, Minn, June 6-9, under the presidency of Dr Melvin S Henderson Rochester The first day will be devoted to consideration of "Open Treatment of Congenital Dislocation of the Hip" Mr W Rowley Bristow, London, as the guest of the association, will deliver an address the second day on "Internal Derangements of the Knee" Other speakers include

Dr William E Gallie Toronto Ont Tendon Fixation in Infantile Paralysis—Late Results
Dr Willis C Campbell, Memphis Tenn Analysis of Living Cases of Bone Sarcoma After Five Year Period
Dr Philip D Wilson Boston Treatment and End Results of Adolescent Epiphyseolysis of the Upper End of the Femur
Dr Hugh T Jones Los Angeles Treatment of Acute Purulent Arthritis by Joint Washing

Saturday morning, the third day will be devoted to presentation of numerous short communications

Society for Study of Rheumatic Diseases—The American Association for the Study and Control of Rheumatic Diseases will hold its annual meeting in Cleveland at the Hotel Cleveland, June 11, 9 a m, when the following program will be presented

Dr Arthur Steindler Iowa City Focal Infection in Arthritis
Dr Charles W Wainwright Baltimore Arthritis and Streptococcus Vaccine Based on Skin Sensitivity
Dr Frank J Sladen Detroit Three Years Concentrated Work
Dr Frank R Ober and Dr William T Green Boston Arthritis in Children
Dr William Paul Holbrook Tucson Ariz Variations in Management During the Different Phases of Atrophic Arthritis
C W Scull Ph D and Dr Ralph Pemberton Philadelphia The Influence of Dietetic and Other Factors on the Reduction of Swelling of Tissues in Arthritis
Dr Joseph Kovacs New York The Peripheral Blood Circulation in Chronic Arthritis and the Influence of Vasodilators
Dr John G Kuhns and Harold L Weatherford Ph D Boston The Role of Reticulo-Endothelial System in the Deposition of Colloidal Dyes and Particulate Matter in Articular Cavities

To be read if time permits

Dr I Maxwell Lockie and Roger S Hubbard Ph D Buffalo Studies on Metabolism of a Case of Gout
Dr Edward F Hartung New York Calcium and Cholesterol Metabolism in Arthritis
Dr G Douglas L Taylor Dr Albert B Ferguson and Dr Haig H Kasabach New York A Study of Roentgenologic Findings in Various Forms of Chronic Arthritis

Psittacosis Control—The development of measures to control psittacosis in the United States was outlined in *Public Health Reports*, April 6, in a report prepared for presentation to the permanent committee of the International Office of Public Hygiene in Paris this month In 1932 there were

seventy-six cases with seven deaths and in 1933 fifteen cases with four deaths. Up to March 4 of this year, only two cases with one death had been reported, but since the report was written an outbreak has been reported from Pittsburgh in which ten deaths occurred. All reported cases were traceable to birds bred in California, according to the report. Importation of parrots into the United States had been stopped by an embargo in January 1930, which was amended in 1932 to include all psittacine birds. Early in 1932 California health authorities placed an embargo on importation of birds into the state and began an epidemiologic study, which showed that the disease had become endemic in California aviaries. Eleven hundred and forty aviaries with about 100,000 parakeets were inspected and registered. Efforts of state authorities to regulate breeding and marketing aroused such opposition that the federal government added a provision to interstate quarantine regulations prohibiting transportation of birds of the parrot family unless shipments were accompanied by a certificate of state health authorities. Strenuous efforts were also made by the California authorities to control spread of psittacosis within the state, but it was found that certificates were being altered and sickly birds were being shipped out of the state. In December 1933 the U S Interstate Quarantine Regulations were again amended to require that no birds of the psittacine family could be shipped in interstate commerce unless such birds were at least 8 months old (it had been determined that young birds are more susceptible to the infection) and unless they were accompanied by a certificate signed by the state health officer and granted after inspection and such laboratory tests as are deemed necessary. A new type of certificate was recently adopted describing in detail the shipment for which it is issued. It is issued in quadruplicate, one copy being sent to the health officer at the point of destination. Thus he is advised of the arrival of birds and may refuse admission to them if it is deemed advisable. Copies of this certificate are filed also with the state health office, the common carrier and the issuing health office.

FOREIGN

Chinese Journal Honors Professor Fülleborn—The *Chinese Medical Journal* dedicated a special parasitology number to the late Prof. Friedrich Fülleborn, director of the Institute for Tropical Diseases, Hamburg, Germany, an authority on medical parasitology. The special number combined the issues for November and December 1933 and contained 400 pages of original articles. Professor Fülleborn, who died Sept. 9, 1933, became interested in tropical medicine as a medical officer in the German Colonial Army in German East Africa in 1896. In 1901 he became a member of the staff of the Hamburg institute for tropical medicine and in this capacity visited many parts of the world for scientific investigation concentrating in later years on helminthology. He became director of the institute in 1930.

Society News—The Society for the Study of Inebriety celebrated its fiftieth anniversary, April 10 with a special meeting at which Sir Humphry Rolleston delivered an address on the history of the society.—The fourth International Convention for Life-Saving Service and for First Aid in Accidents will be held in Copenhagen, June 11-16.—The sixth congress of the International Society for Logopedics and Phoniatrics (therapeutics of speech and voice) will be held in Budapest, September 5-7.—An International Congress for Endocrinology will be held in Marienbad, Czechoslovakia, May 24-26, under the chairmanship of Prof. Julius Bauer, Vienna. Information may be obtained from Professor Bauer, Mariaungasse 15 Vienna, concerning scientific matters and from the Balneological Institute, Marienbad, on administrative and technical matters.

Ophthalmologic Congress in India—The annual conference of the All India Ophthalmological Society was held at the new All India Institute of Hygiene, Calcutta, Dec. 19-21, 1933. Clinical demonstrations were presented in the institute and in the Carmichael Medical College. Among speakers were Lieut.-Col. Ernest William O. G. Kirwan, on epidemic superficial punctate keratitis, Dr. Susil K. Mukerjee, Calcutta, on glaucoma as a result of epidemic dropsy, Lieut.-Col. R. E. Wright, Madras, on Von Hippel-Lindau's disease, Lieut.-Col. J. N. Duggan, Bombay, treatment of external eye diseases with ultraviolet rays and Dr. Victor C. Rambo, Mungeli, the place of tarsectomy and grafting of mucous membrane in surgery of the lid and conjunctiva. The Association for the Prevention of Blindness in Bengal furnished an exhibit of slides and motion pictures illustrating care of the eyes and need for preventive work. Colonel Duggan was elected president. The 1935 meeting will be held in Madras.

The World Typhus Situation—A review of the occurrence of typhus throughout the world during 1932 and 1933 assembled by the Health Section of the League of Nations in *Epidemiological Reports*, showed serious outbreaks in Egypt, both the Asiatic and European territories of the Soviet Union, Syria and Chile. After a decline to less than 300 cases a year the number of cases reported in Egypt rose to 3,236 in 1932 and 7,476 in 1933. The disease appeared for the first time in Uganda in June 1932 and persisted through 1933. Endemic typhus showed a marked increase in the United States, though the increase is partly due to improvement in diagnosis. In South America the disease spread rapidly in Bolivia, Peru and especially Chile during the two years. A severe epidemic occurred in March and April 1932 in Syria among the semi-nomadic tribe of about 2,000 members camped along the Euphrates River, there were more than 400 cases, with 300 deaths. The most important foci in Asia were in the Soviet Union, where after a period of low incidence (less than 2,000 cases in 1928 and the two following years) 27,188 cases occurred in 1932. The number was considerably less in 1933, the report stated. The course in the European part of the union was parallel to that of the eastern region. A few cases were reported in the Irish Free State, Spain and Portugal.

Government Services

Physicians Wanted for Civilian Conservation Corps

The War Department announces that there is a shortage of qualified physicians of the Medical Reserve Corps to meet the needs of the medical service for the Civilian Conservation Corps. This shortage will be aggravated when a new group of approximately 300,000 men will be enrolled for the summer camps, about 200 men to each camp. An officer of the Medical Reserve Corps with the necessary medical supplies to care for the sick and injured will be assigned to each camp or group of camps if located close together. Assignments will be made by the corps area commander under whose jurisdiction the camp is located, for a period of six months, which may be extended at the discretion of the corps area commander. One captain and two lieutenants will be appointed for each thousand men enrolled in the conservation corps. Medical Reserve officers who desire such assignment should apply direct to their corps area commanders. Physicians who are not members of the reserve may secure appointments by applying to the nearest corps area commander or to the Surgeon General's Office, Washington, D. C. Addresses of the corps area headquarters and the states comprised in each are as follows:

First Maine New Hampshire Vermont, Massachusetts Rhode Island Connecticut Headquarters Army Base Boston 9 Mass.
Second New Jersey, Delaware and New York Headquarters, Governors Island N. Y.
Third Pennsylvania Maryland Virginia, District of Columbia. Headquarters U. S. Post Office and Court House, Baltimore
Fourth North Carolina South Carolina Georgia Florida Alabama Tennessee Mississippi and Louisiana. Headquarters Oakland City Station Atlanta
Fifth Ohio West Virginia, Indiana, Kentucky Headquarters Fort Hayes Columbus Ohio
Sixth Illinois Michigan, Wisconsin Headquarters, U. S. Post Office Building Chicago
Seventh Missouri Kansas Iowa Arkansas Nebraska Minnesota North Dakota South Dakota Headquarters Baird Building Omaha
Eighth Texas Oklahoma, Colorado New Mexico Arizona. Headquarters Fort Sam Houston, San Antonio Texas
Ninth Washington Oregon Idaho Montana Wyoming, Utah Nevada and California Headquarters Presidio San Francisco

The pay and allowances of a first lieutenant are approximately \$250 a month. Living accommodations are furnished at the camps for the officer only and at no cost to him. Each camp provides arrangements for mess at a minimum charge. Transportation is furnished by the government from the officer's home and return. Further information concerning appointment to the Medical Reserve Corps or to duty with the Civilian Conservation Corps may be obtained by applying direct to the surgeon of the corps area of which the applicant is a resident.

CORRECTION

Increase in Population—In the State Board Number 6 THE JOURNAL, April 28, page 1402 appears a statement to the effect that the increase in population between 1920 and 1930 was 6 per cent. The sentence should have read, "According to the U. S. Census Bureau the population in 1933 was increasing at the rate of seven-tenths of 1 per cent."

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 14, 1934

The Payment of Hospitals and Physicians for Traffic Accidents

The minister of transport, Mr Oliver Stanley, received a deputation appointed by the parliamentary medical committee (drawn from physicians and surgeons who are members of either of the legislative chambers) in regard to the payment of hospitals and physicians for traffic accidents. The speakers emphasized the urgent need for compensation for services rendered and material loss arising from the treatment of these accidents and suggested the incorporation in the forthcoming bill to deal with traffic accidents of provisions on the lines of the road traffic emergency treatment bill, which has passed through the house of lords (*THE JOURNAL*, January 6, p 55). The minister expressed sympathy with the position of the hospitals and physicians in connection with such accidents. He intimated that the new bill will be so widely drawn that it will be possible for members to move amendments to achieve the object desired. As it is not suggested that the cost should be met from state funds but from the compulsory insurance policies of drivers, there would be no difficulty over a financial resolution. Members of the deputation pointed out that an intolerable position had been reached, that physicians had moved away from houses at busy crossings because they were called out at all hours of the day and night and often received no payment or even thanks. In many instances more than half the beds at cottage hospitals were occupied with bad accident cases, with the result that the local subscriptions were falling away. One of the difficulties, apparently, was that motorists hesitated to make any payment to a physician on the ground that it might be construed as an admission of liability. After the conference, Lord Moynihan stated to the press that he knew of a physician who had attended more than a hundred traffic accidents and had not received a cent. There were over two million licenses and at a cost of 50 cents a year, or less than a cent a week, physicians could be guaranteed a \$3 fee and hospitals could be paid for emergency treatment.

The Falling Birth Rate

Dr E W MacBride, professor of zoology in the Imperial College of Science, in an article contributed to the *Daily Dispatch* expresses satisfaction at the falling birth rate, which he regards as having saved the nation from starvation. Fifty years ago the birth rate in Great Britain was 34 per thousand, today it is 15. As a biologist he finds that, while species of animals and plants vary much in the number of offspring, that number is directly related to the dangers of childhood. The herring lays 20,000 eggs a year, the fulmar petrel only one, yet the average population of the two species remains about the same over a period of years. The egg of the herring is fastened to a stone and then abandoned whereas the egg of the petrel is hidden in a hole till the chick hatches, and this is then carefully tended until it can fly. Obviously the young fulmar has a better chance of living to grow up than the young herring and therefore, to maintain the existing population much fewer of the former are required. In London 150 years ago out of every five children born three died before the age of 5 years. Now the infantile death rate is only 35 per thousand births. If the birth rate had remained at the level of fifty years ago and no emigration had occurred people would have been so closely packed in this island that life would have been impossible. The latitudes in which the white race can live and bring up families are limited and only two of

the British dominions fall within them. Canada is vast but an arctic climate renders four fifths of it unsuitable. Moreover, in the east there is a large granite plateau of 2,000,000 square miles, covered with barren soil and capable of only the poorest kind of farming. Australia is within tropical and sub-tropical zones, and three fourths is rainless desert. The population is only 6 million, of which half is concentrated in the four principal cities. Successful farming is possible only on a strip along the eastern and southern coasts. Nature's law for the benefit of every species is natural selection, which means restriction of reproduction to the most vigorous. But by social services the human race strives to counteract natural selection and then wonders at the size of the unemployment rolls.

The Treatment of Men Burned in Colliery Explosions

The mines department has been exercised by the high mortality of men burned in colliery explosions. During the last two years, out of sixty-two men brought to the surface after explosions forty-five died in hospitals from the effects of the burns. It has been noticed that men even slightly burned have died after being brought to the surface. It is therefore recommended that men who are burned should be carried up on stretchers, well covered with blankets, even though the burns do not appear to be serious. The report shows that nearly all the men found dead in the mine after explosions have died not from the burns they received but from carbon monoxide poisoning. It is therefore thought that those found alive have been affected more or less by this gas. Owing to the serious effect of carbon monoxide on the heart and respiration, it is recommended that a mixture of oxygen containing 7 per cent of carbon dioxide should be administered as soon as possible—if possible, at the place where the men are found. It is also pointed out that in extensive superficial burns, such as are produced in explosions, toxic symptoms come on early—in five or six hours—and are pronounced. To obtain the most rapid result from local treatment by a coagulating agent, a 20 per cent solution of tannic acid in 1,000 acriflavine hydrochloride should be applied.

The Notifiable Diseases in 1933

According to statistics of the federal bureau of health, diphtheria and scarlet fever caused the highest percentage of cases in the German reich in 1933. In comparison with the two previous years, the morbidity and the mortality increased. The adjoining table shows the figures for three years.

	Case Incidence			Deaths			Case Mortality (per Cent)		
	1931	1932	1933	1931	1932	1933	1931	1932	1933
Diphtheria	26,627	64,138	74,559	3,005	2,974	3,698	5.47	4.64	4.97
Scarlet fever	40,980	50,268	76,749	471	307	348	1.00	0.72	0.71

After the apex of the seasonal incidence was reached in the forty-eighth calendar week, the mortality from diphtheria in 1933 was considerably lower than in 1932. The morbidity from scarlet fever was 40 per cent higher than in 1932, without approaching however, the morbidity for 1927, 1928 and 1929 (19,883, 122,225 and 95,909 cases). The increase in the number of deaths from diphtheria and scarlet fever showed about the same ratio as the increase in the number of cases.

The cases of infantile paralysis dropped from 3,733 in 1932 to 1,249 in 1933, and the deaths declined from 315 to 131.

Epidemic cerebrospinal meningitis showed a slight increase. The incidence for the years 1929-1933 was 959, 663, 574, 518 and 598, which resulted in 503, 351, 307, 256 and 279 deaths,

respectively. In the years mentioned, the deaths amounted to 52, 53, 52, 49 and 47, respectively, per hundred cases.

Cases of illness due to meat, fish and sausage poisoning show a further decline for 1933 (1,527 as against 2,477).

The decline in cases of typhoid was 25 per cent, in paratyphoid (although no details were given), 28 per cent, and in dysentery, 48 per cent. The number of deaths from dysentery declined only 3 per cent (from 126 to 122), from paratyphoid, 10 per cent, from typhoid, 28 per cent (from 513 to 369).

The number of persons injured by the bite of animals with rabies, or by animals suspected of being rabid, rose from sixty-four to 132 (one fatal case). There were three cases of glanders and two of trichinosis, with no deaths.

During the previous year, 1932, no cases of rabies or of glanders or trichinosis were notified. The number of cases of anthrax declined from eighty-one in 1932 to seventy-nine in 1933, the number of deaths remained the same (ten).

The cases of childbed fever showed a decline (4,826 cases, 1,379 of which proved fatal), thus, there were 286 deaths to each hundred cases. The peculiarly favorable status of tuberculosis in Prussia (in 1932, only 39,716 cases of contagious pulmonary and laryngeal tuberculosis were notified) was preserved in 1933 there having been only 39,832 notified cases. The number of deaths showed a slight decrease (decline from 20,945 to 20,868).

Increase in the Incidence of Diphtheria

In 1933, as Professor Catel, director of the Kinderklinik announced, not only did the number of persons contracting diphtheria show an increase, but there was also a distinct change in the course of the disease. The highly toxic type of diphtheria with a high case mortality was more frequent than in former years. Since the methods heretofore used for active immunization (Behring's vaccine, toxin-antitoxin mixture, Ramon's anatoxin) are neither absolutely harmless nor certain to produce an absolute immunity the time has not yet come for compulsory vaccination on a large scale. It may be stated that the Lowenstein protective ointment does not appear to be effective.

The Bacterial Flora of the Vagina

Researches that Siebke carried out at the Universitäts-Frauenklinik in Kiel on the bacteriology of the vaginal secretion revealed either pure cultures of streptococci or cultures composed chiefly of streptococci, in 54 per cent of the 1934 gravidas. The presence of streptococci was demonstrated in about 70 per cent of all cases examined. Febrile puerperal disorders, in spite of a normal childbirth, showed the highest percentage in the cases that, during pregnancy, presented in the vagina a pure streptococcus flora, predominantly streptococci, or the latter mixed with *Bacillus coli*. In these puerperants the morbidity was almost three times as high as in women with a pure, or prevailingly pure, *Bacterium vaginalis* flora at the end of term. Foul smelling lochia are less frequently present in association with a pure, or prevailingly pure, *Bacterium vaginalis* flora than with other micro-organisms. According to the cases examined, febrile puerperal disorders following a spontaneous birth are the more rare, the more distinctly the intact acid protection in the region of the vagina is characterized by a corresponding bacterial flora.

The Diagnosis of Lead Poisoning

The pharmacologist Prof. Dr. Behrens, who has for years studied questions pertaining to lead, spoke recently before the Berlin Medical Society. By the use of radioactive lead isotopes, with which he poisoned mice he was able to establish that, contrary to other older views, lead poisoning constitutes a genuine cumulative disease resulting from a difference between the intake and the excretion of the poison. Lead accumulates

chiefly in the liver and kidney, and secondarily in the bones. In the blood there is an adsorption by the red corpuscles. In the bones it is significant that the storage occurs chiefly in the subepiphyseal areas and under the periosteum. By the use of the radioactive lead the demonstration is simple, as the lead produces light spots on a photographic plate. It was possible in this manner to demonstrate that the lead undergoes a rapid resorption and a slow excretion in the animal, and that it is a highly cumulative poison. But, when large quantities are ingested, a considerable portion is not resorbed by the intestine but is eliminated with the feces. The elimination of the stored portions takes place slowly, namely, along with the bile into the intestine and by way of the kidney. The elimination occurs in the form of lead sulphate, which is soluble with difficulty.

Behrens discussed the methods for the demonstration of small quantities of lead. He has adopted the method of H. Fischer, which, by means of a dye (diphenylthiocarbazone), demonstrates colorimetrically lead in quantities as low as thousandths of a milligram. Behrens emphasized that researches must be instituted to discover where the borderline between the normal and the pathologic secretion of lead lies. Until that has been done, it will be impossible to render an expert opinion in questions concerning the degree of disability or amount of compensation.

Promotion of the Early Marriage of Physicians

Among the policies of the new government, the promotion of early marriages plays no small part. The Bavarian minister of the interior has recently taken up the cause of the physicians. A careful examination of medical journals reveals that in advertisements of positions open for physicians there is an occasional cautious statement to the effect that unmarried applicants will receive first consideration. The federal ministry of the interior has issued a new decree concerning the promotion of the early marriage of physicians. Attention is directed to an article by a hospital physician and to the opinions expressed by the federal bureau of health, in which it is emphasized that there exists an absolute necessity and duty to reserve, as a rule, all openings for first assistants, and particularly for head physicians, for physicians who are either married or who plan to marry as soon as a suitable position is secured, furthermore, that, in filling posts for head physicians, preference must be given to applicants who have a large number of children. An inquiry has now been launched to ascertain whether it will be possible to provide homes for such physicians to a greater extent than has been done in the past.

Ten Years of Experience with the Ramon Anatoxin

Mr. G. Ramon, who now occupies, at the Academy of Medicine, the chair made vacant by the death of his teacher Roux, gave a lecture recently in which, as is the custom, he gave a survey of his discoveries. Ten years has elapsed since he proposed diphtheritic anatoxin for immunization against diphtheria. The method today enjoys world-wide acceptance. The immunity that the vaccination produces is demonstrated by the Schuck test and by the amount of specific antitoxin in the blood serum of the persons vaccinated. It is durable, and at the end of five years, the percentage of subjects immunized remains about the same as it was just after the vaccination. In recent years, Ramon has endeavored to increase the efficacy of the vaccination. The method of combined vaccination (anti-typhoid vaccine plus anatoxin), which he developed with the collaboration of Zoeller, answers this double purpose. It thus becomes possible to effect simultaneously two immunizations and to reinforce the immunity secured. Its use is recommended.

by the law of December 1931, which made vaccination with anatoxin compulsory in the army. The adoption of anatoxin of high antigenic value has brought new progress. It requires only two injections and produces an immunity of a high degree. In closing, Ramon declared that with the systematic and general use of vaccination by anatoxin there is hope that diphtheria may be entirely eliminated.

The Harmful Effects of Oil Burning Steamers on Marine Animals

Since mazout has been widely employed for firing the boilers of ships, harmful effects on marine animals have been observed. The petroleum left on the surface of the sea forms a layer that is scarcely perceptible but which, as it is never removed, increases with the years. Prof. Charles Richet has pointed out its effects on sea life in a communication to the Academy of Sciences. A thin coat of mazout covers the most frequented sea routes, particularly in the smaller areas, such as the English Channel and the North Sea, and for years considerable destruction has been observed among the inhabitants of these seas. The plankton, which constitutes the food of many fish, is being destroyed. Oysters are dying by the millions. Many fish are killed when the coating of oil obstructs their gills. The oil impregnates the wings of diving birds and gums up their feathers. As a result, these birds die from the cold. One sees, on the northern coast of France, veritable hecatombs of seagulls. In England, the Society for the Protection of Birds has called the attention of navigation companies to this lamentable destruction. The filters employed recover a part of the oil but allow a considerable part to escape. As these conditions brought about by oil burning vessels are likely to become worse, it may be that, in the course of centuries, important changes will be brought about in the animals of the sea, by this new factor.

An Electric Thermometer for Measuring Surface Temperatures

Mr. Jean Saidman presented recently to the Société des médecins des hôpitaux de Paris an electric thermometer that is accurate, although simple. It consists of two plates that are applied to the point the temperature of which one desires to measure. The electric current produced at the level of these plates enters metal coils connected with a millivoltmeter having a graduated centigrade scale. The figure read on this apparatus must be added to that of a mercury thermometer placed in the metal coils. Only from ten to fifteen seconds is required to ascertain the temperature of any point on the skin or the accessible mucous membranes. The apparatus enables one to study the pathology of the joints, the evolution of arthritis—accompanied by an elevation of temperature that diminishes as the attack recedes. One can study also surface elevations of temperature such as accompany inflammatory attacks or deep congestions.

Radium in the Treatment of Epulis

Degrais published, a few years ago, a report of a case of epulis as large as a walnut which was cured by radium. Since then he has observed a number of cases that were sent to him by dentists, and he has published an article in which he states that radium therapy is the surest treatment for epulis. The technique that he has finally adopted is the following. Under local anesthesia, he implants in the tumor needles from 1 to 2 cc. long and containing from 15 to 2 mg. of radium, depending on the size of the epulis, the needles being more or less numerous, depending on the case. The results were always good, and Degrais has never observed a recurrence. This is an excellent mode of treatment for all forms of epulis.

ITALY

Feb. 15, 1934

Congress of Obstetrics and Gynecology

The twenty-first national congress of obstetrics and gynecology was held at Bari, under the chairmanship of Professor Gaifami, director of the Clinica ostetrica of the Università Adriatica.

The official speaker on the first topic, "Vaginal Celiotomy," was Professor Bertino of Padua. The indications for such an intervention may be divided into obligatory and preferential. To the obligatory indications belong the cases in which the abdominal route is contraindicated and the vaginal route constitutes the only way to cure the disease. In cancer of the cervix, Bertino prefers the abdominal route, in cancer of the corpus and in chorio epitheliomas, the vaginal route. In prolapse of the uterus he limits operative treatment by way of the vagina to the rare cases of neoplastic or hypertrophic uterus or irreducible prolapse. The vaginal route and the Resnelli method are indicated in cases in which retroversion is associated with prolapse of the uterus. In uterine perforations one has recourse to the vaginal route only in clean cases, and in tuberculosis of the genitalia only in cases with frank localization in the uterus. In obstetrics, vaginal celiotomy is reserved for cases presenting hemorrhage due to a remnant of placenta remaining in the uterus, postpartum hemorrhages resistant to other methods, and hemorrhages due to placenta praevia or vesicular mole.

The second topic, "Female Sex Hormones," was introduced by Professor Acconci of Pavia. He emphasized that thus far only the more important aspects of the humoral correlations had been analyzed, whereas no less importance attaches to the features still unknown.

Professor Gaifami spoke on gynecologic radiotherapy, and suggested certain criteria for the regulation of the subject, the need of distinguishing the use of radium from that of roentgen rays, and of soliciting in the field of gynecologic radiotherapy the collaboration of the gynecologist. The congress approved a resolution to that effect.

Professor Gaifami spoke on the development of mother's aid in southern Italy. There is a discrepancy in the number of institutions in northern and southern Italy, to the disadvantage of the latter. The speaker suggested the creation of special obstetric-gynecologic departments in every chief town in the provinces. The birth rate is higher in the South.

For the next congress the island of Rhodes was selected. The two topics on the program are (1) "Woman in Relation to Sport Activities," chief speaker, Professor Scaglione, and (2) "The Lower Segment of the Uterus in Its Anatomic Peculiarities, Its Physiologic Behavior and Its Clinical Importance."

The Treatment of Leukemia

At a meeting of the Società medico chirurgica of Bologna, Professor Viola brought out that the clinical manifestations of the leukemic states differ widely. With regard to roentgen treatment, his experience shows that better results are obtained with small doses administered at varying intervals, depending on the case.

Volta called attention to the determination of the basal metabolism in judging the gravity of the chronic leukemic disorders and for establishing a prognosis. Such a test is useful also in radiologic treatment.

Schassi spoke on the periods of remission in chronic leukemic myelosis. He gave an account of a patient who was subjected to systematic study from 1924 until today, roentgen treatment being applied from time to time. At present he is in good

health The speaker considers the case an example of true clinical recovery

Azzi described cases of lymphopenic lympholeukemia, with an acute course, in which some benefit resulted from blood transfusion

He thinks that some benefit could be derived by directing roentgen rays to the tonsils

Possati, in radiologic treatment of chronic leukemia, follows commonly the technic of applying small fractional doses to the liver and the spleen He noted that some patients who do not react to ordinary treatment received benefit from brief applications of rays in accordance with the Ghilarducci method of variable filtration

Meeting of the Medico-surgical Society of Pavia

The Societa medico-chirurgica of Pavia met recently under the chairmanship of Prof. A. Pensa Filippi and Locatelli reported the results of their trials of vaccino-therapy by the intravenous route in undulant fever, in which they follow the norms indicated by Bianchi They found that this method of treatment is applicable in certain stages of the disease and does not cause untoward incidents It is well to commence with small doses and to increase the dose rapidly so as to provoke a sharp febrile reaction The beneficent effects of the treatment appear early To prevent recurrences it is well to continue the injections after complete defervescence, seven or eight injections being given in all

The Draft of a New Law on Quackery

The Bulgarian Board of Health has transmitted a memorandum to the government, asking for legislative help against quackery, which is flourishing in this country The draft defines quackery as follows (1) When any one without a license to practice medicine undertakes to treat patients professionally, advertises or calls himself a doctor, prescribes or supplies to his patients drugs that a chemist may not sell without a prescription, (2) when a dentist extends his therapeutic activities beyond the realm of dentistry and gives a general anesthetic, for example, or when a specialist in massage treats patients without their being referred to him by a doctor, or a midwife administers a general anesthetic or supplies drugs other than those which she is specifically qualified to dispense, (3) when a doctor, not licensed as a specialist poses in any way as a specialist, (4) when a doctor prescribes an unnecessarily large quantity of drugs solely to profit thereby, or if he advises, exclusively for his own profit, an operation or medical treatment for a disease for which such treatment is obviously unsuitable, or for a disease from which the person concerned is plainly not suffering, (5) when a doctor prescribes drugs ostensibly for medical purposes, although cognizant of their being wanted for other purposes (drugs of addiction), (6) when a doctor lends his name to the advertisement of drugs, medical equipment, foods or drinks in such a way that the public is liable to form an inaccurate opinion as to the real value of said articles, and (7) when a doctor lends his name to the activities of unqualified persons, to make the public believe their medical activities are authorized by him, such persons are guilty of quackery

The Incidence of Echinococcosis in Europe

In a treatise in *Praxis* on the occurrence of echinococcosis in Europe the statement is made that the prevailing opinion that Mecklenburg and Pomerania are the areas most affected needs correction H. Toole, who studied conditions in Greece,

found that in the Piraeus one person in 1,000 had an echinococcal infection, whereas in Mecklenburg the rate is only 1/3,585, while the population of Rostock (the city with the most extensive incidence in Mecklenburg) shows a rate of 1/1,370 In the province of Cephalonia the corresponding figure is 1/529 Echinococcal cysts have been found in 23 per cent of necropsies in Athens, whereas in Rostock during the period 1861-1905 the percentage was 1.98 and in 1905-1922 only 0.57 Dikoff, who studied the conditions in Sofia in Bulgaria, states that in 9,770 necropsies between 1900 and 1908 the echinococcus was the cause of death in four, or 0.49 per cent In 1922, out of 780 necropsies, death in seven cases was found to be due to the echinococcus R. Peicic, who has collected the cases in Yugoslavia in the last ten years, found 921 cases, including 241 from Bosnia and South Serbia Peicic regards Greece as one of the most badly infected of European countries According to Dew, the disease is uncommon in England

In Hungary, Czirer analyzed all the cases observed in the surgical clinics in 1917-1927 and found that echinococcal infection accounted for 0.2 per cent of the total He observed that echinococcal cysts are much more prevalent among the rural than among the urban population While human infection is not more prevalent in Hungary than in the western countries, Drs. Bodrogi and Lorincz, who studied the spread of echinococcosis in Hungary, consider it advisable to take strong measures against the echinococcus here as elsewhere

Massage Establishments

According to a responsible Bucharest newspaper the public health authorities have issued an order that will put an end to grave abuses in massage establishments and at the same time regulate their sphere of action It was explained that this restriction was necessary because massage establishments had become the haunts of secret vice According to the new regulations, massage can be practiced on persons only of the same sex and only on healthy subjects, the so-called curative massage being allowed only under medical supervision Cosmetic massage without the use of electrical appliances may be practiced freely The order subjects professional masseurs to special examination, and no licenses to practice will be given to applicants who have been punished for any offenses

BELGIUM

Feb. 27, 1934

Certification of Specialists

The title of "medical specialist" gave rise recently to a discussion before the Academy and various medical societies The discussion is not yet closed, but the Societe belge d'ehirurgie has unanimously supported the resolution of Professor de Beule affirming the need of creating a special surgeon diploma, which, without depriving the doctors of medicine surgery and obstetrics of the rights that the law confers on them, will emphasize the need of postgraduate training for those who aspire to an official post of surgery in a hospital or a clinic The technical and scientific advances in surgery demand imperatively the creation of a certificate guaranteeing that the holder has acquired a thorough knowledge of surgery by special studies

Exanthematous Typhus

Bruynoghe and Jadin have presented a communication to the Royal Academy of Medicine on exanthematous typhus They isolated the virus from rats caught in the port of Antwerp It is therefore not impossible that sporadic cases of exanthematous typhus may appear in that port or elsewhere The

virus of exanthematous typhus may adapt itself to other rodents (mice, dwarf mice, voles), and these rodents may play a part in the dissemination of the disease. The Weigl vaccine confers evident protection against typhus and should be applied whenever general health measures are insufficient to protect against contaminations.

Hospital Organization

At the third International Congress of Hospitals, the committees appointed to study the organization and equipment of hospitals under the chairmanship of Dr. Alter reached the following conclusions:

In order to secure the best results from hospital organization, small hospitals must be avoided, and all possible influences must be made to combine to promote the physical and psychic personality of the patients. Hospital care and treatment will not attain the maximal effectiveness unless they center on the individual patient.

The hospital of the future must be conceived on a large scale from the point of view of plan and organization, but in spite of its size it must guarantee the most complete individualization in the treatment. These two conditions, if realized, will result in the maximum economic efficiency.

From the administrative point of view, the best type of hospital is that containing about 600 beds. Smaller hospitals should be planned so that they can be enlarged and made to approach the ideal type without any excessive outlay.

The best type of 600-bed hospital should consist of absolutely distinct departments the collaboration of which is possible without friction. The arrangement should be such as to prevent loss of time in going back and forth between the departments. As far as possible, the patient should not be moved but rather the personnel and the equipment.

Large wards are excluded. Rooms with several beds are not practical. Rooms with one or two beds are the ideal. To attain this, a service unit comprising twenty-five beds, the majority of the rooms with only one bed should be adopted. The rooms should open on a central corridor. The equipment of the sickrooms and of the service units should conform in all respects to the fundamental principles stated.

Aid for Natives of the Congo

The Queen Elizabeth Fund for the medical relief of the natives of the Belgian Congo was established as a result of the endowment of a medical fund to combat tropical diseases in the Belgian Congo. The income from this endowment is to be used by the Queen Elizabeth Fund to provide medical aid for the natives. The report of the Queen Elizabeth Fund in 1931, which has just appeared, can be expected to give only a general idea of the society's mode of functioning. The directive agencies in Belgium are the administrative council and the committee on management, with a permanent office in Brussels. There is an executive committee, presided over by the governor general of the Belgian Congo, and an executive bureau, at present in the province of Congo Kasai. Besides the detection and the treatment of diseases, and prophylaxis and hygiene in general, the program includes the application of measures designed to promote the well being and growth of the native population. The program comprises also the protection of the mother and child, the crusade against social diseases, industrial hygiene, and the like. In 1932 the crusade against social diseases was exceedingly energetic as regards rashes and syphilis. The number of new tripanosomic infections is diminishing steadily and has dropped to below that of 1931, namely, to 0.26 per cent. The medical personnel attached in 1932 to the sector of the Lower Congo comprised twenty-two physicians (fifteen in 1931) and fifty-two sanitary officers and nurses (thirty-nine in 1931).

Marriages

STANLEY MORTIMER DILLENBERG, Newark, N. J., to Miss Margery Jean Siegel of New York, April 19.

ROBERT LAURENCE KNIPFER to Miss Marian Kathleen Knapp, both of Brandon, Iowa, March 13.

ALLEN CLAY GWIAN JR. to Miss Mary Virginia Homan, both of El Paso, Texas, April 25.

MAI THOMAS BOLOTIN, Chicago, to Miss Mary R. Mann of Shanghai, China, February 25.

JOSEPH B. PRIESTLEY to Miss Elizabeth Jane Lutz, both of Des Moines, Iowa, April 14.

CLARENCE G. POOL, Compton, Ill., to Miss Helen Schnuckel at New Orleans, March 27.

Deaths

Harry Lee Barnes of Wallum Lake, R. I., University of Vermont College of Medicine, Burlington, 1898, past president of the Rhode Island Medical Society, member of the American Climatological and Clinical Association, formerly director of the National Tuberculosis Association, at one time superintendent of the Stony Wold Sanatorium, Lake Kashaqua, N. Y., superintendent of the Rhode Island State Sanatorium, aged 56, died, April 8, of heart disease.

Thomas E. Hodges, Rogers, Ark., Arkansas Industrial University Medical Department, Little Rock 1888, formerly professor of osteology, College of Physicians and Surgeons, Little Rock, professor of anatomy, histology and embryology, and lecturer on anatomy, University of Arkansas School of Medicine, Little Rock, formerly mayor of Rogers, aged 74, died, March 25, of influenza and myocarditis.

William Gardiner Anglin, Kingston, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1883, M.R.C.S., England, 1884, emeritus professor of clinical surgery, Queen's University Faculty of Medicine, fellow of the American College of Surgeons, formerly physician to the Kingston Penitentiary, aged 77, died, February 4.

Charles Edward Caldwell, Cincinnati, Medical College of Ohio, Cincinnati, 1884, professor emeritus of surgical anatomy, University of Cincinnati College of Medicine, member of the Southern Surgical Association, formerly on the staff of the Cincinnati General Hospital, aged 73, died, March 23, of coronary thrombosis.

Julius A. Chevigny, Hammond, Ind., School of Medicine and Surgery of Montreal, Que., Canada, 1895, member of the Indiana State Medical Association, secretary of the board of health of Hammond, on the staff of St. Margaret's Hospital, aged 61, died suddenly, March 17, in Austin, Texas, of coronary occlusion.

David Nowlin, Montgomery City, Mo., St. Louis Medical College, 1890, member of the Missouri State Medical Association, fellow of the American College of Surgeons, bank president, aged 67, died, March 5, in a hospital at St. Louis, of chronic nephritis, diabetes mellitus and gangrene of the right foot.

Wilkin Blackburn Stevens of Kimball, W. Va., Maryland Medical College, Baltimore, 1904, past president of McDowell County Medical Society, formerly member of the Public Health Council, medical director of the Stevens Clinic Hospital, aged 56, died, March 8, at Coral Gables, Fla. of coronary occlusion.

James O. Ringold, Winona, Miss., University of the South Medical Department, Sewanee, Tenn., 1897, member of the Mississippi State Medical Association, past president of the Winona District Medical Society, on the staff of the Winona Infirmary, aged 60, died, March 31, of arteriosclerosis.

Arthur Henry McCreight of Fort Dodge, Iowa. Rush Medical College, Chicago, 1897, past president of the Webster County Medical Society, served during the World War, formerly county coroner, aged 67, on the staff of St. Joseph's Mercy Hospital, where he died, March 28, of pneumonia.

Richard Benson Stewart, Warren, Pa., College of Physicians and Surgeons, Baltimore, 1881, member of the Medical Society of the State of Pennsylvania, on the staff of the Warren General Hospital, aged 72, died, March 25, of pneumonia as the result of an accidental fall.

John Richard Benton, Stevensville, Md. University of Maryland School of Medicine, Baltimore, 1883, for twenty years member of the county board of education and for twelve years judge of the orphans' court, aged 75, died, March 19, of chronic nephritis and heart disease

Henry Dixon Stewart, Monroe, N. C., University of Maryland School of Medicine, Baltimore, 1898, member of the Medical Society of the State of North Carolina, served during the World War, aged 62, was found dead in bed, March 20, of heart disease

Perry Gabriel Dunlap, Lawton, Okla., Vanderbilt University School of Medicine, Nashville, Tenn., 1881, University of Nashville Medical Department, 1882, member of the Oklahoma State Medical Association, aged 75, died, January 21, of angina pectoris

Byron Stanley Loney ♂ Detroit, University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1917, fellow of the American College of Surgeons, on the staff of the Harper Hospital, aged 50, died, March 17, of coronary thrombosis and arteriosclerosis

Benjamin Beamer Morrow, Spiceland, Ind. Eclectic Medical Institute, Cincinnati, 1897, member of the Indiana State Medical Association, aged 61, died, February 27, in the Methodist Episcopal Hospital, Indianapolis, of prostatic hypertrophy

Ernest Charles Daniel MacCallum, Kingston Ont., Canada, McGill University Faculty of Medicine Montreal, Que., 1897, associate professor of medicine, Queen's University Faculty of Medicine, aged 61, died, February 6, of pneumonia

George Frederick Bainter, Strasburg, Ohio, Ohio Medical University, Columbus, 1896, formerly mayor of the village and county coroner, served during the World War, aged 63, died, March 31, in the Union Hospital, Dover, of myocarditis

John Charles Humphreys ♂ Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1908, Jefferson Medical College of Philadelphia, 1910, formerly a medical missionary, aged 54, died, March 31, of hypostatic pneumonia

Robert Thomas Dott, Sioux Falls S. D. Rush Medical College Chicago, 1883, Bellevue Hospital Medical College New York, 1885, member of South Dakota State Medical Association, aged 75, died, January 3, of cerebral hemorrhage

Joseph Francis Brewer, Minneapolis, Kan. University Medical College of Kansas City, 1889, member of the Kansas Medical Society, for many years president of the board of education, aged 79, died, March 11, of lobar pneumonia

Helmer Walter Huseby, Floodwood Minn. University of Minnesota Medical School, Minneapolis, 1926, member of the Minnesota State Medical Association, aged 34, died March 22, in a hospital at Duluth, of pneumonia

Robert McCune Smith, Kansas City, Mo., Kansas City Medical College, 1902, member of the Missouri State Medical Association, aged 72, died, March 18, in the Research Hospital, of carcinoma of the left jaw, liver and brain

William Sheppard Norman ♂ Hamburg, Ark. University of Louisiana Medical Department, New Orleans, 1875, past president of the Ashley County Medical Society, aged 82, died, March 13, of hypostatic pneumonia

Peter Paul Klopp, Philadelphia, Jefferson Medical College of Philadelphia, 1890, member of the Medical Society of the State of Pennsylvania, also a lawyer and pharmacist, aged 66, died, March 24, of arteriosclerosis

Howard Banks Ames ♂ Alva, Okla. Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901, past president of the Woods County Medical Society, aged 60, died, March 14, of carcinoma of the stomach

Harry A. P. Neel, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, aged 79, died, February 5, of uremia and arteriosclerosis

Linn Bayard Marshall, Portland, Maine University of Colorado School of Medicine, Denver, 1913, member of the Maine Medical Association, served during the World War, aged 51, died, March 30, of heart disease

Kenneth Bowles Huffman, Joplin Mo., St. Louis University School of Medicine, 1910, member of the Missouri State Medical Association, served during the World War, aged 50, died, March 12, of angina pectoris

Clarence Atwood Baker, Portland, Maine, Medical School of Maine, Portland, 1882, member of the Maine Medical Association, aged 82, died, March 30, in St. Barnabas Hospital of strangulated inguinal hernia

Wladyslaw Josef Alfons Schwarz, Jersey City, N. J., Eclectic Medical College of the City of New York, 1902, member of the Medical Society of New Jersey, aged 73, died, March 4, of angina pectoris

Edgar Oriel Newlin, Fontanet, Ind., Physio-Medical College of Indiana, Indianapolis, 1904, served during the World War, aged 57, died, February 5, in the Union Hospital, Terre Haute, of pneumonia

Samuel Freeman Hassler ♂ Harrisburg, Pa., Jefferson Medical College of Philadelphia, 1894, aged 65, for many years on the staff of the Harrisburg Hospital, where he died, March 21, of heart disease

John Denver Siddall, Carey, Ohio, Eclectic Medical Institute, Cincinnati, 1898, member of the Ohio State Medical Association, served during the World War, aged 61, died, March 15, of pneumonia

William Hill Black, Kansas City, Mo. (licensed in Oklahoma under the Act of 1908), member of the Oklahoma State Medical Association, aged 63, died, February 28, of endocarditis and cholecystitis

William M. Long, Liberty, S. C., Medical College of the State of South Carolina, Charleston, 1896, member of the South Carolina Medical Association, aged 65, died, March 19, of coronary thrombosis

George Morrison Logan ♂ Akron, Ohio, Rush Medical College, Chicago, 1909, served during the World War on the staff of the City Hospital, aged 55, died suddenly, March 21, of heart disease

West Montgomery Carson, Clarksdale, Miss., New York Homeopathic Medical College and Hospital, 1893, veteran of the Spanish American War, aged 62, was shot and killed, Dec. 19, 1933

Robert Burton Newcomb, Cleveland, Western Reserve University Medical Department, Cleveland, 1893, also a lawyer, aged 61, died, March 19, of an incised wound of the throat, self inflicted

Edward William Nolan, Toronto, Ont., Canada, Queen's University Faculty of Medicine Kingston, 1916, served during the World War, aged 43, died, February 25, of cerebral hemorrhage

John Rupert Elliott, Palacios Texas, University of Texas School of Medicine, 1902, veteran of the Spanish-American and World wars, aged 55, died, February 10, of coronary obstruction

Irving Solby, Boston Harvard University Medical School, Boston, 1907, formerly on the staff of the Massachusetts General Hospital, aged 53, died suddenly, March 26, of heart disease

Peter Andrew Snell, Baltimore, University of Rochester (N. Y.) School of Medicine, 1933, aged 27, an intern at the Johns Hopkins Hospital where he died, March 14, of pneumonia

Michael Sheridan McGauran, Lawrence, Mass. Rush Medical College, Chicago, 1888, member of the Massachusetts Medical Society, aged 86, died, March 25, of arteriosclerosis

Walter Waverly Scott ♂ Kensington, Kan., University Medical College of Kansas City, 1906, served during the World War, aged 53, died, March 18, of bronchopneumonia

George Vernon Harecourt, Powassan Ont., Canada Trinity Medical College, Toronto, 1896, member of the legislature, aged 59, died, February 1, in Toronto, of coronary thrombosis

Lucy Anne Kirk, Boston Boston University School of Medicine, 1893, aged 75, died, April 5, in the New England Deaconess Hospital of coronary infarct and diabetes mellitus

Foster Strong Haven, Manasquan N. J., College of Physicians and Surgeons Medical Department of Columbia College, New York, 1886, aged 75, died, March 8, of heart disease

Oswald F. Henning, Los Angeles, Rush Medical College, Chicago, 1904, served during the World War, aged 55, died, March 19, of peritonitis due to perforating gastric ulcer

TINTED LENSES

To the Editor —In THE JOURNAL, April 14, page 1223, appeared an article by C H Coblentz, which should meet with enthusiastic approval. The misinformation he discussed has been allowed to go rampant too long without challenge. It is time for the bunk about tinted lenses to be properly aired.

Except for emergency wear, under extreme light conditions, tinted lenses have no legitimate use. They are distinctly harmful when worn constantly, cultivate an acquired photophobia to normal light, and are then no longer sufficient protection against glare. They are totally unnecessary when the correction is right.

Advertising illustrations usually show the wearer comfortably facing glaring light through tints but carefully avoid suggestion of the reduced vision in ordinary, and especially subdued, light, or of the light sensitiveness that follows.

Perfected lenses are excellent and are worthy of more truth in advertising. Claims are made by the manufacturers that through these lenses marginal vision is as good as the central. This claim is largely false. Marginal vision is obtained by turning the eye in the orbit, the muscle pull alters the shape of the globe, and vision is slightly distorted. Obviously, no lens can possibly allow for such distortion. These lenses are useful in high degrees of error, chiefly because of more perfect vertex refraction. In low errors they are little, if any, better than the standard toric, and certainly not worth the additional cost when price must be considered.

I W HAUGHEY, M D, Fort Collins, Colo

THE TYPES OF HUMAN HYPER-SENSITIVENESS

To the Editor —In the article by J A Rudolph and M B Cohen (THE JOURNAL, March 24) the authors distinguish between the reaction in "the artificially sensitized, or anaphylactic man," and "the naturally sensitized man, or man with atopy." They base this distinction primarily on whether or not a history of inheritance can be obtained. The reliance on a negative history as the principal criterion for this distinction is open to criticism because of failure in many cases to obtain satisfactory histories. In my clinical studies on this subject (THE JOURNAL, May 30, 1931, p 1848, Feb 6, 1932, p 446, Ann Int Med 7 1308 [April] 1934), I believe I have clearly demonstrated that the clinical manifestations and the mechanism of these reactions are fully identical whether or not one is dealing with pollen (atopics) or with horse serum (often artificially sensitized) or with any other protein or nonprotein containing antigen.

In the "anaphylactic" man, "the antibody differs from that found in atopy." So far the antibodies in "anaphylactic" and "allergic" shock in men have not been demonstrated. The excellent work of Cooke and Spain, quoted by the authors, includes serum sickness but neither human "allergic" nor "anaphylactic" shock. I have repeatedly tested patients for reagins after "allergic" shock following pollen injections but have never been able to determine these antibodies in the blood soon after shock. Walzer records a similar observation following shock due to an injection of horse serum.

Anaphylactic "sensitivity never produces asthma, hay fever, eczema, urticaria, or other related clinical manifestations of atopy." In the literature, this is a highly controversial question which is not supported by experimental evidence (Ratner, Bret, Jackson, H C, and Gruehl, Helen L. Respiratory Anaphylaxis, Am J Dis Child 34 43 [July] 1927).

The statement that in "anaphylactic" individuals the reactions are less severe, while in atopic ones they may be serious and fatal, is not in accord with clinical observations. In my series of eight deaths following injections of horse serum, which I collected in the state of Michigan, only two gave a previous history of allergy. This would rather indicate that, in fatal cases, "anaphylactic" shock prevails. I have clearly brought out that regardless of whether the sensitized state is acquired or inherited, the severity of a reaction depends primarily on the degree of sensitivity, on the proportion of the overdose to this sensitivity and on the mode and rapidity of absorption (intravenous, backseepage into punctured vein).

Those investigators who share the dualistic conception of atopy and anaphylaxis seem to disregard entirely the fundamental work of Ratner on this subject. The attitude on this question is characteristically expressed by Zinsser, who states in his book (*Resistance to Infectious Diseases*, ed 4, New York, Macmillan Company, 1931) "Were it not for the possibility of confusion in nomenclature [italics mine] we would change this heading [human idiosyncrasies, atopy, allergy] to 'human anaphylaxis,' believing that these conditions in man are based on an immunological mechanism basically identical with anaphylaxis in animals, superficially modified by human anatomical conditions." This matter, I believe, is of more than academic interest because of its bearing on sudden, heretofore unexplained death (*Am J Dis Child* 47:41 [Jan] 1934).

GEORGE L. WALDBOTT, M.D., Detroit

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

STATISTICAL DATA IN HUMAN ANATOMY

To the Editor—In our daily newspaper (*Grand Rapids Press*) an item caught my eye in the section on "This Curious World." The statement is made that the blood vessels of an adult have a combined length of about 100,000 miles. May I ask you whether this statement has the backing of scientific authority? For a long time I have wanted to know whether any estimates have ever been made of the combined length of nerves of the body and of the blood vessels. Also whether the total number of white and red corpuscles has ever been estimated. These figures would be of interest in talks to the public which I sometimes give. If there is any publication you recommend along this line I will be grateful.

A. W. WOODBURN, M.D., Hastings, Mich.

ANSWER—Estimates of the total length of blood vessels in the adult human body would necessarily be only approximate. Krogh, in his book on the capillaries, has made a calculation of the total length of blood capillaries in the muscles. He states that there are more than 100,000 kilometers of capillaries in the muscles alone (62,000 miles). Since the muscles constitute only about 40 per cent of the weight of an adult healthy body, it would be conservative to estimate the total length of all capillaries in the rest of the body at 38,000 miles. Therefore, the statement that there are more than 100,000 miles of blood capillaries seems to be conservative.

No estimates of the total length of nerve fibers in the human body seem to have been made but several estimates have been made of their number. Vierordt estimates the number of nerve fibers in the spinal nerve trunks at over 800,000, the number of fibers in the cranial nerves from the third to the twelfth inclusive, at 200,000 (*Krause's Anatomy*). The number of fibers in the optic nerve have recently been counted by Arey (1934), the two (right and left) together in the human adult contain about 2,600,000. This gives a total of 3,600,000 fibers without the olfactory nerves. These figures are undoubtedly far too small, because the older counts were made by methods that did not permit observation of the finer fibers. Since many of these nerve fibers branch repeatedly toward their termination, the number of fibers in the nerve trunk would be only a fraction of the total number of nerve fibers in the periphery.

The number of red corpuscles in the body has been estimated at twenty-three million million (Vierordt). The proportion of

white blood cells to red cells is about 1 to 666, so that the blood contains only about thirty-three thousand million white cells.

A good reference book for statistics of this kind is Vierordt's *Anatomische, physiologische und physikalische Daten und Tabellen*, Jena, Gustav Fischer, 1906. A considerable amount of such information is contained in Harvey's *Simple Lessons in Human Anatomy*, Chicago, American Medical Association, 1931.

CLIMATIC RECOMMENDATIONS IN SINUS INFECTION

To the Editor—Given chronic sinusitis (probably streptococci) with rheumatoid arthritis together with intermittent low grade fever and tachycardia but no endocarditis in a man, aged 39 otherwise in good health, with arthritis of two years duration and the tonsils removed is choice of climate or operation better to effect a cure of the sinusitis? Would operation be contraindicated because of an occasional bout of fever? Nose and throat specialists seem very much confused about chronic sinusitis and its treatment. If pus is not found at the time of examination in the sinuses they doubt whether infection is present. However, I think that if the nose feels stuffy most of the time if the mucosae of the sinuses are thickened if mucous cysts are present if the nose stops up at night and the throat becomes irritated by discharge or by cold air not adequately warmed and humidified by passing through the sinuses and if a mucoid or mucopurulent discharge sometimes containing a little blood, is present especially on awakening in the morning one can be assured that he is suffering from chronic sinusitis and all the more certain if systemic infection is present. Please omit name.

M. D., Illinois.

ANSWER—Rheumatoid arthritis with a low grade fever in a patient between 20 and 40 is usually associated with a septic focus. In such cases there is a tendency to rapid pulse with low blood pressure. Fever is no contraindication to operation. The absence of pus in the sinuses at the time of examination is no indication that infection is not present. In such cases it is not unusual to find a thickened and infected membrane, nasopharyngeal inflammation and mucopurulent discharge with blockage of the nose. Removal of foci of infection is generally regarded as a first consideration, not at all an easy matter in nasal sinus disease. If the patient is so circumstanced that he can live in a suitable climate, operative treatment could be limited at first to securing adequate drainage. Following this, favorable hygienic surroundings including fresh air and sunshine, constitute an important factor in recovery.

TREATMENT OF SYPHILIS

To the Editor—March 1, 1933, a couple aged 25 and 23, with secondary syphilis consulted me. The husband stated that he had a chancre two and one-half months prior to the appearance of the rash. A Kahn test was made on both of them, the report was 2 plus on him and 3 plus on her. Each of them received twelve injections of sulpharsphenamine intramuscularly in a dosage of 0.6 Gm. at intervals of seven days and 1 drachm (4 Gm.) of a 50 per cent mercurial ointment daily six days out of seven. They became symptomless and felt normal. I discontinued treatment for six weeks and took another Kahn test which was reported negative for both of them. I prolonged the rest period for an additional two months and took another Kahn test and that one also was negative. I prolonged their rest period for four more months and then the Kahn test showed a 3 plus for both of them. Kindly advise me how and for how long to treat them in order to bring about a cure.

M. D., Illinois

ANSWER—The mode of procedure outlined in this question is a classic example of what not to do for a patient with early syphilis. The most recent investigation by the Clinical Cooperative Group and the United States Public Health Service indicates that the principal source of serologic irreversibility and relapse, together with neurorecurrence, is the introduction of rest intervals into the first eighteen months of treatment for early syphilis. During this period, patients should be continuously under treatment with either an effective arsphenamine or a heavy metal such as bismuth, or both. The practice of depending on serologic tests for the cessation or continuance of treatment in early syphilis is pernicious and certain to result in prolonged infectivity and therapeutically unmanageable cases. Such patients should be treated by a scheduled system that will give them approximately forty injections of either arsphenamine or neoarsphenamine and not less than five ten injection courses of an effective bismuth preparation such as bismuth salicylate, during the eighteen months period of treatment. The serologic tests of course should be taken periodically, but their reversal to negative should not be taken as a signal for the cessation of treatment. Regardless of the schedule mentioned treatment should be continued for one year after all symptoms and signs of the disease have disappeared including the finding of a completely negative spinal fluid examination. It should

be mentioned, moreover, in connection with this question that sulpharsphenamine is not a satisfactory drug for the treatment of adult syphilis, on account of the high incidence of dermatic and purpuric hemorrhagic reactions

If the two patients mentioned in the foregoing question are simply positive on the blood and negative on the spinal fluid at this time, an effort should be made to complete the type of treatment, continuous in schedule, which has just been described. The probabilities are that it will be very difficult to reverse the blood serologic tests to negative, and these patients may easily join the category of Wassermann-fast syphilis. Under no circumstances should they be dismissed from observation over a period of years, and the possibility of pregnancy in the woman should be controlled and treatment administered during the pregnancy in order to prevent the birth of a syphilitic child

INJECTION OF VARICOSE VEIN AND TREATMENT OF PHLEBITIS

To the Editor—A woman aged 41 with three children aged 19, 17 and 14 years had varicose veins and phlebitis developing after the birth of the second child seventeen years ago. She had attacks of phlebitis again four and two years ago. She had a fourth attack lately and is just getting over it. She is otherwise in good health. Her blood pressure has always been normally rather low—systolic 100 diastolic 45. There are moderate varicosities of the saphenous vein in the upper third of the calf. It has given little or no trouble at other times. I have not dared to inject anything into the vein on account of the recurring phlebitis. Do you think injection treatment will be advisable and if so how long after the last attack? Would you advise ligation of the saphenous vein or excision to prevent the danger of embolism? How great is the danger of embolism in a case of recurrent phlebitis? Or would you advise to leave well enough alone the patient being rather well and just out of bed now. Please omit name. M D New Jersey

ANSWER—The mere fact that a patient has had phlebitis is not a contraindication to the injection treatment of varicose veins. Her low blood pressure is not a contraindication. The recent attack of phlebitis may be an entirely separate attack and in no way related. They are entirely separate infections and not a flare up of a latent infection. One might wait at least three months before starting the injection treatment and using the electric baker and hot packs alternately a great deal of the time. Ligation should be done in the foramen ovale and the distal saphenous vein injected at the same time. A supportive bandage should be kept on the lower leg for several days following and then those veins should be injected at one sitting. One need not worry about the danger of an embolus in this case.

REACTIONS AFTER ARSPHENAMINE

To the Editor—During the last six months a number of patients who have been receiving neoarsphenamine have developed reactions. These reactions are of the delayed type occurring from one to four hours after the treatment and consist of severe chills, body pains, prostration and sometimes nausea or vomiting. The reactions are somewhat similar to those seen following the first one or two injections of neoarsphenamine when the patient is started on treatment in the secondary stage. The reactions in question have occurred in patients who are receiving their second or third courses of neoarsphenamine and who previously had no trouble following their injections. My maximum dosage is 0.6 Gm. and these reactions frequently follow smaller amounts such as 0.3 or 0.45 Gm. These reactions have lately been occurring in about 20 per cent of the cases under treatment. I have been using D R L neoarsphenamine and have lately changed to Squibb's neoarsphenamine without noticing any particular lessening of the reactions. Some of these patients are able to tolerate Searle's neoarsphenamine which I am informed does not contain the methyl radical. Can you inform me as to the probable cause of these reactions? While I have always had an occasional patient exhibit hypersensitiveness to this drug I have never before had such a high percentage of reactions. The neoarsphenamine is injected intravenously according to the accepted technique the powder being dissolved in double distilled water and the injection being given very slowly. These patients show no evidence of dermatitis and apparently are able to tolerate an indefinite number of the injections if they are willing to put up with these unpleasant reactions. Different samples of the drug from different batches apparently produce the same effect but the reaction is less with the smaller dosages. Kindly omit name and address. M D Ohio

ANSWER—Reactions of the type described, which do not disappear when the brand of neoarsphenamine is changed suggest the following possibilities:

There may be a technical error in the mixing of the drug. This includes a wide range of possibilities such as contaminated solution, aeration of the drug in mixing, undue agitation and glassware not completely cleaned so as to remove all oxidation products of the drug before the next injection is given. Such difficulties creep in when technicians are employed in an office or a clinic and a change from a more experienced to a less experienced person takes place.

While the rate of injection may also be a factor, rapid injection of the arsphenamines is more prone to give rise to acute vascular reactions following immediately on the injections than to delayed reactions, with chill, fever and gastro-intestinal symptoms.

It must also be considered that there are unaccountable factors in the reactivity of groups of patients from year to year and from season to season and that anxiety factors, poor nutrition, a high carbohydrate intake, and the like, are prone to increase the incidence of reaction and reduce the tolerance of large groups of persons receiving treatment for syphilis. Neglect of instructions regarding light meals just before and for twenty-four hours after treatment may at times be responsible for gastro-intestinal reactions.

As a suggestion for dealing with the situation, the neoarsphenamine, following the recommendation of Colonel Harrison and others, might be made up in 10 cc of a 10 per cent sterile solution of calcium gluconate, which can be obtained in ampule form from the larger pharmaceutical manufacturers. This is said by various observers to reduce materially the incidence of gastro-intestinal reactions. Again, it is important to emphasize that the drug must be given at an extremely slow rate.

DANGERS OF COMMON DRINKING CUP

To the Editor—From a sanitary standpoint I am anxious to know your opinion regarding the use of a public sacrament cup in taking communion. I have given information to a minister who advanced the argument that there is a sufficient amount of alcohol in the wine to act as an antiseptic or protective agency. Not knowing the percentage of alcohol I doubted this statement and am writing you for further information. Kindly omit name. M D Nebraska

ANSWER—The same objections apply to the use of a public communion cup as apply to the use of any common drinking cup. There is no reason to believe that any amount of alcohol present in the wine would act as a protective agent. The percentage of alcohol is too small to expect much germicidal action, the time of exposure is too short, and only part of the contaminated area of the cup would be touched by the wine.

DIAGNOSIS OF UNDULANT FEVER

To the Editor—In making a diagnosis of undulant fever in patients who show the clinical symptoms suggesting the disease I should like to know how high the titer must be in the serologic test before the diagnosis can be safely made. Please omit name and address. M D New York

ANSWER—Diagnostic significance is usually attributed to agglutination in dilutions of 1:80 or above. It cannot be said, however, that there is any arbitrary diagnostic agglutination titer. While the serums of most individuals who exhibit a more or less well defined clinical picture of undulant fever will show agglutination in titers of 1:80 or above, occasional cases will be encountered in which no agglutinins are present or agglutinins will exist in titers of from 1:10 to 1:40. Ordinarily, serum agglutinins do not appear until a week or ten days after the onset of illness. In some cases, however, agglutinins may not appear for several weeks. The titer reaches varying heights during the acute course of the disease and tends to fall as the fever abates. Agglutination in dilutions of 1:160 to 1:1,280 will usually be found during the fourth or fifth week of illness. Many persons will retain antiabortus serum agglutinins for many months or years while in other cases they will entirely disappear a few months after recovery.

About 5 per cent of individuals with undulant fever, including those from whom the organism has been recovered from blood culture, will fail to develop antiabortus agglutinins. In occasional instances, agglutination in titers below 1:80 will be encountered in persons from whose blood *Alcaligenes* organisms have been recovered. In cases in which the clinical manifestations are strongly suggestive of undulant fever the absence of agglutinins or the presence of agglutinins in titers of 1:10 to 1:40 should stimulate further serologic and bacteriologic studies. The skin test is of value in differentiating cases in which agglutinins are absent or are present in low titer. If the agglutination test is repeatedly negative and if the skin test is negative, it is quite probable that the patient does not have undulant fever. One method of carrying out the skin test is by the intradermal injection of 0.1 cc of saline suspension of heat-killed or formaldehyde-killed abortus organisms adjusted to a standard of two billion organisms per cubic centimeter. The *Alcaligenes* (*Brucella*) *melitensis* (abortus) vaccine which is available through trade sources, may be used for the skin test. A positive test is characterized by the gradual development, usually within from twenty-four to forty-eight hours

after injection, of an indurated reddish area, usually about 2 to 4 cm in diameter. The induration usually persists for many days or weeks.

Carpenter and others have demonstrated that antiribortus agglutinins develop only when there has been actual invasion of the tissues by living *Alcaligenes* organisms. Subclinical *Alcaligenes* infections have occurred in some persons who have been exposed to the disease, antiribortus agglutinins have been demonstrated in the serums of such persons in the absence of clinical signs or symptoms of undulant fever.

PROFUSE PERSPIRATION AS SIGN OF
GIANDULAR DISTURBANCE

To the Editor—A white woman aged 40 some weeks ago had a moderately severe bronchitis and cough. She is nervous and quite obese weighing about 200 pounds (90 kg). Under ordinary treatment she has recovered from the respiratory infection but now she complains bitterly about profuse sweats which come on mostly at night when she is asleep. When she goes to bed she feels well but at about 1 or 2 o'clock she is awakened from sleep by a profuse sweat which lasts until about 4 o'clock when she falls asleep and does not sweat any more until the next day when she has periodic sweats. Sweating during the day is not apparently brought on by nervousness but when she begins to sweat she becomes nervous. She does not drink an abnormal amount of water and her appetite is normal. She also says that her voice becomes hoarse toward evening even though she does not use it during the day for long periods. Atropine seems to make the patient worse because it produces marked nervous symptoms. Her temperature is normal and she has no evidences of tuberculosis. The blood pressure is 130 systolic 70 diastolic. The pulse rate is 96. Her obesity is probably due to hypopituitarism. I have questioned her thoroughly with special reference to weakness, nervousness and hunger but these symptoms are not present. There seems to be some abnormality of the nervous control of the sweat glands. Do you believe that pituitary gland therapy would help? If so what preparation and what dose would you suggest? I would appreciate any therapeutic suggestion that you will make. Please omit name.

M D Ohio

ANSWER—The analysis of this report suggests that the sweating is a complication of the acute respiratory infection from which the patient has just recovered. This is not an unusual phenomenon and usually will disappear after the lapse of a little more time. If the symptoms were due to the glandular disturbance it is rather difficult to understand why they should not have come on until after the respiratory infection. On the other hand, there are numerous instances of glandular unbalance in which sweating is a pronounced and marked symptom. Such an instance is seen in the menopause. Therapy is usually difficult, the various endocrine products may be used more or less experimentally.

TYPHOID DEATHS IN CHICAGO

To the Editor—What year before the drainage canal was in use did Chicago have the greatest number of deaths from typhoid? How many deaths were reported? How many infections were reported and what was the population that year? What year after the drainage canal was in use did Chicago have the fewest deaths from typhoid? How many infections were reported? What was the population that year? I am writing a paper for a public health talk at a church and would appreciate anything that you can give me on the effect of sanitation in lowering the death rate and the disease rate from typhoid or any other disease.

G E HENSCHEN MD Sherman Texas

ANSWER—The largest number of deaths from typhoid ever recorded in Chicago was in 1891, when 1,997 deaths from this cause were reported. The estimated population in that year was 1,148,710, making a typhoid death rate of 173.8 per hundred thousand inhabitants. This contrasts with average typhoid death rates in later years as follows:

	Typhoid Death Rate per 100,000
1906-1910	15.8
1911-1915	8.2
1916-1920	2.4
1921-1925	1.4
1926-1930	0.6
1931	0.6
1932	0.4
1933	0.4

The population of Chicago was about three times as large in 1933 as it was in 1891, so that if the same rate had obtained in 1933 as in the earlier year there would have been nearly 6,000 deaths from typhoid, whereas there were actually 12. The number of deaths is considered a better measure of the prevalence of typhoid than the number of cases reported. In general, there are approximately ten to fifteen cases for each death.

Much information on the effect of sanitation in lowering death rates will be found in the files of THE JOURNAL and the *American Journal of Public Health* as well as in modern books on hygiene.

North Dakota January Report

Dr G M Williamson, secretary, North Dakota State Board of Medical Examiners, reports the oral, written and practical examination held in Grand Forks, Jan 2-5, 1934. The examination covered 13 subjects and included 100 questions. An average of 75 per cent was required to pass. Three candidates were examined, 2 of whom passed and 1 failed. One physician was licensed by reciprocity and 3 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year	Grad	Per Cent
University of Minnesota Medical School	(1932)	78	5	(1933) 80

Book Notices

Treatment in General Practice By Harry Beckman M.D. Professor of Pharmacology at Marquette University School of Medicine Milwaukee. Second edition. Cloth \$10. Pp 889, with illustrations. Philadelphia & London: W B Saunders Company 1934.

In revising this new edition of his popular book, Dr Beckman has been particularly concerned with two objectives—the elimination of unestablished and discarded methods and the addition of well established new methods. He lists as certain entities not previously included acetylsalicylic acid (aspirin) poisoning, agranulocytosis, blackwater fever, bronchomycosis, erythema, erysipelas, food allergy, gasoline and kerosene poisoning, luecap, hyperinsulinism (hypoglycemia) and dysinsulinism, hypothyroidism without myxedema, lead poisoning, lymphogranuloma inguinale (climatic bubo), malnutrition, methyl chloride poisoning, onchocerciasis, oriental sore, dermal and mucocutaneous leishmaniasis, prophylaxis of gonorrhea in the female, serum sensitization and desensitization, simple achlorhydric anemia, strongyloid infection, tear gas burns, tetany, varicose ulcer, and a section on vehicles and incompatibilities. This volume established itself promptly as a practical work in therapeutics. The revision of the book has increased its merit. One finds the section on the treatment of amebic dysentery quite abreast of the time and in accord with the new literature developed as a result of the recent Chicago outbreak. In the treatment of the common cold, which the author discusses under the title of catarrhal fever, he

mentions all the time tried empirically tested remedies that are available. He does not hesitate to mention proprietary products, although he limits himself in the majority of instances to those which have been credited by New and Nonofficial Remedies. Indeed, he quotes this work repeatedly in his discussions of new remedies. In many instances almost the whole of certain discussions is direct quotation from published literature, most of it from THE JOURNAL. The volume is an excellent compilation in which the author has chosen with good judgment and in which he does not hesitate to criticize on the basis of his own practical experience.

Hypertension and Nephritis By Arthur M. Fishberg M.D. Associate Physician to Beth Israel Hospital New York City. Third edition. Cloth Price \$6.50. Pp 668 with 40 illustrations. Philadelphia: Lea & Febiger 1934.

Perhaps no textbook on these complicated and controversial subjects has been so favorably received by the profession as the work of this author. The book is now in its third edition although the original edition was available only a few years ago. Facts on both subjects, ordinarily difficult of correlation are integrated in such a well organized manner that the reader is able for the first time to get a clear understanding of the symptom complex. This is a most important contribution since the vast majority of patients who suffer from hypertensive and renal diseases are cared for by those in general practice. Almost every chapter in this edition has undergone revision. Some of the discussions that have been added since the last edition are those on the nature and treatment of renal and hypertensive disease in pregnancy, allergy and hypertension, the use of acacia in edema, the therapeutic use of magnesium sulphate and salyrgan, and renal lesions accompanying various forms of endocarditis. This book is invaluable to those engaged in the practice of medicine, as it represents one of the most comprehensive works on the subject. It is written from the point of view of clinical medicine and serves as well at the bedside as in the library.

Essentials of Hospital Practice: A Guide for Students and Interns By Royal M. Calder M.D. Instructor in Medicine Duke University School of Medicine, Durham North Carolina. With a section on Surgical Methods By C. E. Gardner, Jr. M.D., Assistant Professor of Surgery Duke University School of Medicine. Fabrikoid Price \$2.75. Pp 262 with 9 illustrations. Durham: Duke University Press, 1934.

About a year ago the American Medical Association published a handbook for interns. Jointly prepared by the Council on Pharmacy and Chemistry and the Council on Medical Education and Hospitals, it was almost entirely devoted to improving the character of hospital prescribing by encouraging interns, at the outset of responsible practice, to continue the use of rational therapeutics as they had been taught in medical school. Some ready reference data were included. In Calder's book, a list of drugs is included but as only one of a number of important aspects of hospital treatment. Treating the subject quite extensively, he divides his material about evenly between physical and laboratory diagnostic methods and routine and emergency treatments of medical and surgical patients. This handbook should be an excellent investment, as much on the basis of continuing usefulness as the filling of an immediate need. The complete index and convenient pocket size are attractive features.

Die Digitalisbehandlung Von Prof. Dr. Ernst Fdems. Second edition. Paper. Price 7 marks. Pp 154 with 80 illustrations. Berlin & Vienna: Urban & Schwarzenberg 1934.

This volume on digitalis therapy is an instructive and useful work, well arranged and well written. It is particularly prepared for the clinical worker and gives a satisfactory summary of the experimental work. Examples of the laboratory and clinical observations in this work are the following conclusions found in the first and in the next to the last chapter.

Chapter I "In frog's hearts, digitalis has shown a systolic and a diastolic effect in nontoxic doses. I. Systolic effect. 1 The systolic tension and shortening of the muscle fibers is quickened. 2 The systolic shortening of the muscle fibers is increased. II Diastolic effect. 1 The duration of diastole is lengthened. 2 The diastolic relaxation of the muscle fibers is increased and diastole deepened (?). The heart in warm blooded animals observed mechanically shows the same

effect from digitalis as does the frog's heart. It pulls itself together in systole more rapidly and forcefully. It dilates in diastole for a longer time and perhaps also in a greater degree, but now follows an important difference, the lengthening of diastole and the slowing of the pulse that is associated with it occur in pronounced form only if the heart is connected through its vagus nerves to the central nervous system. We must conclude from this (1) that the pulse slowing in warm blooded animals in the main depends on stimulation of the vagus center and (2) that the peripheral digitalis effect in warm blooded animals works in some other way than in the case of the cold blooded animals."

Chapter X "The effective strength of a preparation of digitalis for man must be determined on man himself. The effectiveness of different digitalis preparations should never be determined through the comparison of their effects in different patients, but only through their comparison in the same patient."

For the test of effectiveness of digitalis preparations, such cases are most suitable in which the evident systolic effect of digitalis can be measured, that is, cases of heart weakness with evidences of stasis which afford an opportunity for definite measurements. Every sick heart has its own digitalis dosage."

The Lyophilic Colloids (Their Theory and Practice) By Martin H. Fischer Professor of Physiology in the University of Cincinnati and Marian O. Hooker Research Associate in Physiology in the University of Cincinnati. Cloth Price \$4.50 Pp 246 with 84 illustrations Springfield Ill. & Baltimore Md. Charles C. Thomas 1933

This book is not, as one might judge from its title, a general treatise on the lyophilic colloids. It is concerned entirely with work done by the authors during the last fifteen years on certain types of colloid systems. The book is divided into three parts. The first part, which occupies about two thirds of the book, is on the general nature of the lyophilic colloids. In this part the authors present the results of their work on phenol/water, soap/water, gelatin/water and casein/water systems and develop their thesis that the behavior of such systems indicates that they are not solutions of X in water, but of water in X. The second part deals with chemical applications and the final one with biologic applications. The last section, especially, contains numerous statements which are in direct conflict with all accepted views in this field. This book is interesting mainly because it presents a summary of the work and views of the authors. As a presentation of modern concepts concerning the colloidal nature of protein solutions, it would seem to be inadequate. There are no references to work of such men as Sørensen, Svedberg or Krøyt, who have carried out extensive physicochemical and colloidal studies on proteins, and the latest reference to Pauli is twenty years old. It is too restricted in its point of view to give the reader a satisfactory picture of the theory and practice of lyophilic colloids.

Lettsom: His Life, Times, Friends and Descendants By James Johnston Abraham. Cloth Price 30/- Pp 498 with 145 illustrations London William Heinemann Ltd 1933

When any sick to me apply
I physics bleeds and sweats em,
If after that they choose to die
Why Verily!

I Lettsom

The fame of this couplet is world wide and any psychologist might from it alone have much to say about the character of its author. The Quaker physician concerned was a philanthropist and a man of letters who met every one worth meeting in the London of his time, a man who was equally at home in the presence of the king and among the sick in the city prison. His time was that of Hogarth, Dick Turpin, Fothergill, William Cullen, Benjamin Franklin, John Graham the charlatan, Dr Johnson, Edward Jenner and many others. In this atmosphere Lettsom was active as a medical practitioner, an investigator and a citizen. He founded a medical society, wrote many books on medical subjects, led the campaign for prison reform, founded a convalescent hospital at the seashore, aided Edward Jenner in his campaign for vaccination, and eventually died from a streptococcal infection sustained during a postmortem examination. Lettsom is particularly interesting to Americans because he was himself born in the West Indies and because he was constantly in communication with Ben-

jamin Rush, Benjamin Waterhouse and Benjamin Franklin, all great names in the development of American science. This volume is one of the most fascinating medical biographies thus far available. It is full of anecdotes and personal correspondence and gives a fine picture of an eighteenth century physician who endeavored to fill to repleteness the various capacities in which physicians may serve the public. The book is beautifully illustrated with innumerable portraits and facsimiles of documents of historical interest.

Starling's Principles of Human Physiology Edited and revised by C. Lovatt Evans D.Sc. F.R.C.P. Jodrell Professor of Physiology in University College London. The chapters on the Central Nervous System and Sense Organs revised by H. Hartridge M.A. M.D. Sc.D. F.R.S. Professor of Physiology at St. Bartholomew's Medical College. Sixth edition. Cloth Price \$8.75 Pp 1122 with 562 illustrations Philadelphia Lea & Febiger 1933

In the twenty-two years since the first edition of this physiology became available there have been six editions and a Spanish translation. This should be sufficient testimony to the merit of the work and to its appreciation by teachers in this field. In the present edition there have been extensive alterations and rewritings in order to bring the work down to date. The chapters on the circulation, nervous system and sense organs have been revised by Professor Hartridge. A few references have been added to the work in order to provide the reader with modern bibliographic material. Dr Evans points out that at least 4000 papers on physiology are published each year. It would no doubt be simple to point out the failures of the work in regard to certain modern types of investigation. In the section on sleep, for example, there are no references to the recent American investigations on the depth and intensity of sleep or to the use of modern electrical recording devices and motion picture apparatus for such studies. In the section on the blood the suggestion is offered that the blood platelets may be artefacts, yet a few pages farther on there is a serious discussion of their part in blood coagulation. On the whole, however, the work is highly competent, complete and probably as safe a work in the field it concerns as any now available.

Obstetrics and Gynecology Edited by Arthur Hale Curtis M.D. Professor and Head of the Department of Obstetrics and Gynecology Northwestern University Medical School. Volume III and General Index to Volumes I to III. Cloth Price \$35 per set Pp 1201 with 570 illustrations Pp 137 Philadelphia & London W. B. Saunders Company 1933

The third volume of this notable system of gynecology and obstetrics is well up to the standard of the previous two volumes. Here the sections included are on displacement and relaxations, disturbances of function, the endocrines in gynecology and obstetrics, special diseases and important symptom complexes, other gynecologic diseases and symptom complexes, and special topics. The final section is for the general reader, one of the most valuable in the entire work. It includes not only an outline of the methods of examination but also the application of the x-rays, blood transfusion, anesthesia and operative management and the relation of obstetrics and gynecology to other branches of medical science. This volume like the others, is extensively and beautifully illustrated, and there is an adequate index.

La cura specifica delle brucellosi Da Prof. G. di Guglielmo et al. Società medicochirurgica di Catania. Paper Price 15 lire Pp 167 with illustrations Catania Vincenzo Muglia 1933

Sponsored by the Medicochirurgical Society of Catania under the editorship of Professor Guglielmo, a number of eminent clinicians and research workers, among them the pathologist Fichera, a collective review has been published on the specific treatment of brucellosis. A better title than the one using the word "specific" would be "The Biologic Treatment of Brucellosis," since the work is limited to the study of intravenous vaccine therapy of the various clinical forms of brucellosis, including parabrucellosis infection. The various contributions make up a unit of well connected pleas for the value of bacterial vaccines in these infections, and particularly for the intravenous administration instead of the conventional subcutaneous or interdermal uses. Well controlled observations seem to indicate that clinical results amounting to well defined clinical cures have been obtained after four or five injections.

The doses used have been one million killed bacteria for the first injection. The injections have been administered every four or five days in amounts of one hundred million, increasing to from ten to fifty millions at each injection. Dr. Guglielmo reports thirty cases, which were uniformly cured in from seven to eight injections, establishing for that group a record of 100 per cent results. The meningo-encephalic manifestations of brucellosis as well as cases of vegetative endocarditis with degenerative myocarditis are discussed, and anatomopathologic material from necropsies is well presented. On the whole, the review is of extreme interest and replete with good therapeutic suggestions.

A Practical Medical Dictionary of Words Used in Medicine with Their Derivation and Pronunciation Including Dental Veterinary Chemical Botanical Electrical Life Insurance and Other Special Terms. Anatomical Tables of the Titles in General Use. The Terms Sanctioned by the Basle Anatomical Convention and Those Suggested by the Nomenclature Commission. Pharmaceutical Preparations Official in the U. S. and British Pharmacopoeias and Contained in the National Formulary and Comprehensive Lists of Synonyms. By Thomas Lathrop Stedman, A. M., M.D. Twelfth edition. Leather. Price \$7.50. Indexed. \$7 without index. Pp. 1256 with illustrations. Baltimore: William Wood & Company, 1933.

This authoritative work is now in its twelfth revised edition. In the introductory note it is pointed out that it contains about a thousand new titles, which would indicate that the medical language grows by at least one word a day. All the changes of the British Pharmacopoeia of 1932 are indicated, and also changes in anatomic nomenclature. The present issue is thirty-three pages longer than previous issues of what is already one of the most complete medical dictionaries available. Notwithstanding the fact that the publication is dated August 1933, one fails to find reference to ascorbic acid or to dinitrophenol.

The Physician as Man of Letters: Science and Action. By Thomas Kirkpatrick Munro, M.A., M.D., Regius Professor of Medicine in the University of Glasgow. Cloth. Price 10/6. Pp. 212. Glasgow: Jackson, Wylie & Company, 1933.

For many years the author has been collecting data relative to medical men who distinguished themselves in other ways than in the practice of medicine. Nevertheless the work is quite incomplete. It would require far more study and research than the author has been able to give to this subject to supply an adequate list of names. His list is particularly weak so far as concerns Americans, and, strangely enough, he is even deficient in his list of British physicians who have made distinguished names in other fields. In his section on poets one finds Sir Robert Bridges, George Crabbe, Oliver Goldsmith, Keats and John McCrae. One seeks in vain under dramatists for the name of Arthur Schnitzler. Among his writers of fiction one finds Conan Doyle, but missing are Arthur Conan Doyle, Somerset Maugham and Francis Brett Young. His list of ambassadors and statesmen fails to include Geddes, Ramon y Cajal and Virchow. It is amusing to note the physicians who have been pirates and the names of noted criminals. The volume is an interesting beginning of what might be developed into a highly important work.

To Be or Not to Be: A Study of Suicide. By Louis I. Dublin, Ph.D., Third Vice President and Statistician, Metropolitan Life Insurance Company, and Bessie Bunzel, M.A., Research Assistant, Statistical Bureau, Metropolitan Life Insurance Company. Cloth. Price \$3.50. Pp. 443 with illustrations. New York: Horlison Smith & Robert Haas, 1933.

The gradual increase in suicide which has brought self destruction up to a place among the first twenty in the list of causes of death, is a problem that concerns not only the medical profession but workers in all the social sciences. Although the literature, both periodical and book, is extensive, it is safe to say that Dr. Dublin's volume constitutes the most competent word thus far offered on the subject. He considers suicide from the historical point of view. He is concerned with its prevalence with the influence of environment and with its relationship to life insurance. He discusses its psychology and the methods of prevention. The points of view of the various churches are considered as well as the legal aspects. The volume is supplemented by a series of tables presenting the fundamental data. There is also an adequate index. Dr. Dublin sees the answer to the problem of suicide in a more general distribution of the good things of life, a change in our economic system and a more widespread application of education in mental hygiene as well as in the practice of those branches of medicine which deal with problems of personal adjustment.

History of the University of Edinburgh 1883-1933. Edited on Behalf of the History Committee by A. Logan Turner, M.D., LL.D., F.R.C.S. Published for the University. Cloth. Price 10/- Pp. 452 with 27 illustrations. Edinburgh: Oliver and Boyd, 1933.

One of the most distinguished universities in the world deserves fully the biography here made available. The biography has been written by professors in various departments and concerns each of the special schools, containing as well a section on the university portraits and on the life of the student community. This volume is essentially supplementary to the previous one, entitled "The Story of the University During Its First Three Hundred Years," published in 1884. The book is beautifully printed, handsomely illustrated and supplemented by a number of appendices giving biographic notes, donors and similar lists. Of special interest to the medical profession is the chapter on the faculty of medicine, by Prof. John Dixon Comrie. It provides not only a list of each of the men who held the chairs in various departments and of their contributions to medical periodical literature but also some excellent portraits and estimates of the Edinburgh contribution to medical progress. Most important of those included are Sir William Turner and Lord Lister.

Laboratory Medicine: A Guide for Students and Practitioners. By Daniel Nicholson, M.D., Assistant Professor of Pathology, University of Manitoba. Second edition. Cloth. Price \$6.50. Pp. 569 with 127 illustrations. Philadelphia: Lea & Febiger, 1934.

This useful book on laboratory diagnosis is now available in a thoroughly revised edition. The first edition was published four years ago and was well received by the profession. While little of the material has become antiquated in this short time the author has revised and brought each subject to the present. Many new procedures have been added. The revised edition reflects the manner in which the author has anticipated the need of practicing physicians. The chapter on the choice of tests to confirm or disprove their diagnosis has been considerably amplified with new material on the more common conditions seen in practice. This book is highly recommended to the medical student and practicing physician for information on the indication, method and interpretation of laboratory tests that are particularly adapted to the complete study of the patient. It is perhaps one of the most practical and concise textbooks of laboratory medicine in any language.

Medicolegal

Hospitals: Right of Employee to Bind Employer for Payment of Hospital Bill.—About 2 o'clock in the morning, March 29, the back of an employee of the defendant was broken in the course of his employment. The manager of the defendant's plant, where the accident occurred, directed the night engineer, who was in charge of the plant at that time, to call a physician. He called one of the two physicians designated by the defendant's insurance carrier to serve in such emergencies. When the physician found that the injured workman's back had been broken, he directed that his patient be sent to a hospital. The night engineer then summoned an ambulance and the injured man was taken to the plaintiff's hospital, where he remained until he died.

On June 6 more than two months after the patient had been admitted, attorneys for the defendant's insurance carrier notified the hospital that neither the employer nor his insurance carrier would be responsible for any hospital bills in excess of the hospital's proportionate share of \$200, the limit of liability for medical services imposed by the Kansas workmen's compensation act on employers. Subsequently, on June 20, a bill for \$272.40 was sent to the injured workman and on September 15 a bill for \$710.45 was made out against him. The latter bill was not delivered, for the injured workman, whom the hospital had continued to care for, had died the preceding day. Apparently, demand was then made on the employer but payment of anything in excess of \$75 was refused. The insurance carrier represented that that amount was the hospital's share of the money payable by the employer, under

the workmen's compensation act for medical treatment. The tender was rejected and action brought against the employer for the amount of the bill. Judgment was given in favor of the hospital. The employer appealed to the Supreme Court of Kansas.

The hospital contended that under the circumstances of the case there was an implied agreement by the employer to pay the bill for the services rendered its injured employee. The Supreme Court, however, held to the contrary, holding that the night engineer, on whose order the employee was taken to the hospital was not authorized to bind his employer for payment. The fact that the manager of the defendant's plant told the engineer to call a physician did not prove that he directed the engineer to bind the company to pay hospital bills. Said the court:

Authority to bind the corporation for medical services etc. either for employees or for others who are injured in the course of the operation of a railroad is not ordinarily to be inferred from the duties of a subordinate agent or employee such as a conductor, a station agent, a roadmaster, a yardmaster, an engineer or an attorney for the company." 144 C J 455

The Supreme Court therefore reversed the judgment in favor of the plaintiff and directed the trial court to enter judgment in favor of the employer.—*St. Mary's Academy v. Railways Ice Co. (Kan.)* 26 P (2d) 278

Workmen's Compensation Acts Undulant Fever Contracted in Caring for Infected Cattle Compensable—The claimant, Crowley, a dairy instructor in the Idaho Industrial Training School, had to supervise and handle the school's dairy herd. Some of the cows were infected with contagious abortion. At calving time he removed the afterbirths with his bare arm and in the same manner after the calves were born he treated the cows with disinfectants. Some time after he had been so engaged he was stricken with undulant fever and was ill for several months. The industrial accident board of Idaho, however, denied his claim for compensation under the workmen's compensation act, because of legal technicalities, and he appealed to the district court, Fremont County. That court decided the technicalities in his favor, found that the undulant fever from which he was suffering had been contracted in the course of his employment, and reversed the order of the industrial accident board that denied him compensation. His employer thereupon appealed to the Supreme Court of Idaho.

His employer contended that the undulant fever from which Crowley suffered was an occupational disease not an accident and therefore was not compensable under the Idaho act. The Supreme Court pointed out, however, that his disability had resulted from his exposure to contagious abortion in treating the cattle suffering from that disease, that other employees who handled the cows did not become infected, that the usual source of undulant fever is through the human digestive tract by taking raw fat [sic] or milk, and that contracting undulant fever by direct contact with cows carrying its infective germ because they are suffering from contagious abortion is an infrequent occurrence. In *Ramsay v. Sullivan Min Co.* 51 Idaho 366, 6 P (2d) 856 the Supreme Court of Idaho said:

An occupation or industry disease is one which arises from causes incident to the profession or labor of the party's occupation or calling. It has its origin in the inherent nature or mode of work of the profession or industry and it is the usual result or concomitant. If therefore a disease is not a customary or natural result of the profession or industry, per se but is the consequence of some extrinsic condition or independent agency the disease or injury cannot be imputed to the occupation or industry and is in no accurate sense an occupation or industry disease.

In the present case said the Supreme Court, if the injury sustained by Crowley was not an injury inherent in his occupation as commonly understood, but an accident in the popular and ordinary sense of the word, as denoting an unlooked for mishap or untoward event which is not expected or designed, his claim for compensation cannot be denied on the theory that the injury resulted from an occupational disease and not from an accident. The Supreme Court accordingly affirmed the award in favor of the infected employee.—*Crowley v. Idaho Industrial Training School (Idaho)*, 26 P (2d) 180

1 For cases holding substantially contrary to the holding of the Supreme Court of Kansas in this case see: *Page v. Thomas (Texas)* 47 S W (2d) 894 J A M A 100 365 (Feb. 4) 1933 *St. Barnabas Hospital v. Minneapolis*, 68 Minn 254 70 N W 1126

Current Medical Literature

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Demonstration of Articular Facets in Lumbosacral Backache—In obtaining an oblique view of the articular facets in sciatic and lumbosacral pain Ghormley and Kirklin have the patient, lying supine on the table, turned slowly to an oblique position, toward the side to be examined until the transverse axis of the pelvis is at an angle of 32 degrees with the horizontal. To effect this precise angulation, a rectangular piece of stiff cardboard, measuring 10 by 12 inches (25 by 30 cm), with a concave lower edge to accommodate the lower part of the abdomen, is employed. On the cardboard is a line drawn radially from the center of the concave lower edge and marking an angle of 32 degrees with the vertical. The tips of the concave edge are applied to the iliac spines the cardboard is held in an approximately perpendicular plane and the position of the patient is adjusted by means of sandbags and cushions. The tube carriage, equipped with a cone 6 inches (15 cm) in length and an aperture of 3½ inches (9 cm), is swung into position and the axis of the rays is directed vertically to the midpoint of Poupart's ligament on the elevated side. This point also lies almost vertically over the opposite articular facets of the fifth lumbar vertebra and they will be depicted approximately in profile. The table is equipped with a flat Potter-Bucky diaphragm and speed screens are employed. A target film distance of 30 inches (76 cm) 65 peak kilovolts and 40

milliamperes of current is used. The time of exposure is varied in proportion to the thickness of the patient's body. The important points that may be observed by an oblique view of the articular facets are (1) narrowing of the space between the articulating surfaces of the facets, (2) marginal proliferation about the articulating surfaces of the facets indicating hypertrophic changes or in many instances traumatic arthritis, (3) fractures through the surfaces of the facets or through the adjacent laminae and pedicles, (4) increased roentgenability of the bony structures making up the facets and their supporting structures and decreased roentgenability of these structures. All these changes may be observed in cases of chronic pain in the back in which no other pathologic change is known to exist than the localized traumatic arthritis that causes these syndromes. Besides these changes, one may observe in these roentgenograms changes in the vertebral bodies and intervertebral disks. One should also note that the sacro-iliac joint is presented in a new aspect and one which may possibly lead to more accurate determination of lesions there.

Radiosensitive Neuroblastoma—Hauser presents a case of neuroblastoma that was sensitive to radiation therapy. Although the patient died of recurrence, the author thinks that radiation therapy may prove to be of value in future cases. The dosage factors used were 200 kilovolts, 30 milliamperes, 0.5 mm of copper filtration, 50 cm target skin distance for the neck and pelvis and 70 cm for the chest. The author believes that earlier recognition and earlier radiation therapy would possibly have given the patient a better prognosis or perhaps a cure and that small, divided doses extended over a period of several weeks with a greater total dosage would have possibly brought about permanent regression.

Radiation Therapy of Keloid—Hodges states that thick old keloids should be removed surgically and postoperative irradiation given. Radium and roentgen radiation are equally efficacious in the treatment of this condition, but the large area of the body surface usually involved makes roentgen radiation the method of choice in the majority of cases. He has obtained excellent results with from 250 to 300 roentgens of unfiltered rays, from 80 to 90 kilovolts every four to six weeks. The large doses in general use have not been necessary. The most important factor in the treatment of keloid is the institution of proper irradiation in the early stages of the disease while the cells composing the growth are radiosensitive. When there are unsightly deformities, irradiation will usually relieve the contractures without surgery, but when there are broad white bands of dense fibrous tissue in addition to the scars, these bands should be removed surgically.

Arsenoxide in Relation to Toxicity of Arsphenamine—Schamberg and his associates found the naphthoquinone color test (Rosenthal) for arsenoxide to be highly sensitive for the detection of this substance in solutions of arsphenamine and neoarsphenamine aerated with oxygen or exposed to the air. The test is much less sensitive for the detection of arsenoxide in the tissues after the administration of the arsphenamines. After the intravenous injection of 0.1 Gm of arsphenamine in rabbits arsenoxide was found in the liver in about 0.5 mg per gram of tissue and in about 0.1 mg per gram of kidney. None was found in the muscles. After the intravenous injection of 0.2 Gm of neoarsphenamine per kilogram of weight, arsenoxide was found in about 0.3 mg per gram of kidney, but none

in the liver or muscles. With smaller amounts of arsphenamine and neoarsphenamine, arsenoxide could not be detected in these tissues. Freshly prepared solutions of arsphenamine and neoarsphenamine do not contain detectable amounts of arsenoxide by this test. When approximately 34 per cent of arsphenamine in alkalinized solution was oxidized into arsenoxide with oxygen, the toxicity was about doubled. The amounts of arsenoxide in solutions of neoarsphenamine produced by oxygenation or exposure to air did not correspond as closely with the results of toxicity tests as observed with oxidized solutions of arsphenamine. One lot of neoarsphenamine free of arsenoxide was unusually toxic for the rat. When a solution was oxygenated, the production of arsenoxide was about the same as observed with lots of neoarsphenamine of much lower toxicity. The presence of arsenoxide in solutions of arsphenamine and neoarsphenamine tends to shorten the latent period for trypanocidal effects when injected intravenously into rats with trypanosomiasis but does not appreciably change the minimal curative dose per kilogram of weight as compared with freshly prepared solutions free of arsenoxide. In some tests with neoarsphenamine the presence of arsenoxide appeared to reduce the minimal curative dose. The presence of approximately 34 to 36 per cent of arsenoxide in solutions of arsphenamine and neoarsphenamine not only hastened spirocheticidal effects in rabbits with acute testicular syphilis but reduced the minimal curative dose of each compound about one half. It appears that arsenoxide is more spirocheticidal than trypanocidal.

Treatment of Neurosyphilis with Acetarsone (Stovarsol).—Spiegel used acetarsone intravenously in the treatment of twenty-five patients presenting various types of neurosyphilis over a period of seventeen months. Injections of 1 Gm were given either weekly or twice weekly according to the patient's ability to come for treatment. The initial dose was in all cases from 0.25 to 0.5 Gm for the first three or four doses. The injections were given continuously with no rest periods; the more intensive use of acetarsone seems to offer more encouraging results. In the asymptomatic group the Wassermann reaction on the spinal fluid was reduced from positive to negative in two patients and to doubtful in two others. In one patient a strongly positive fluid with 0.2 cc was reduced to 0.8 cc. In two the negative reactions remained the same. The serologic tests on the blood showed slightly greater positivity in one case following treatment, three remained negative and three showed lessened positivity. The cell count was reduced in all cases, usually after six to ten injections. The protein and globulin content of the spinal fluid was reduced and approached normal figures in all but one case. In six the changes in the colloidal gold curve remained approximately the same, one changed from the first to the second zone. In the group of patients suffering from tabes dorsalis, seven were definitely improved and two had advanced optic nerve changes. The Wassermann reaction of the spinal fluid became negative in these two cases. In two the Wassermann reaction of the spinal fluid was negative in one and plus-minus in the other before treatment was instituted, in four the positive reaction was reduced to negative in two and decreased in the other. In one patient the strongly positive fluid was considerably reduced in all factors. The cell counts varied from 0 to 105 and corresponded to the usual observations of this group, with the exception of one case in which the cell count was unusually high. The protein and globulin fractions gave low figures in all but one case, in which it was increased as the result of accidental contamination of the blood. The serologic tests on the blood were reduced from strongly positive to negative in four, two were negative and remained so, one slightly positive became negative, and another strongly positive was slightly reduced. In the group of six meningovascular patients the Wassermann reaction of the spinal fluid was reduced from positive to negative in two, and in the remaining four the strongly positive fluid showed lessened positivity. The cell counts ranged from 1 to 37. The colloidal gold curves were not distinctive. The protein and globulin was slightly increased in four and considerably increased in two. A decrease in the solids was noted in all the patients. Serologic tests on the blood were reduced from strongly positive to negative in two, and in another the positivity was reduced. One negative reaction remained so, one strongly positive reaction showed no change and one doubtful reaction became negative.

*Irrigation in Treatment of Disease of Frontal Sinus Anatomical Study of Nasofrontal Connections O. E. Van Alstyne Chicago—p. 224

Irrigation in Disease of Frontal Sinus.—Van Alstyne points out that the procedure of catheterization of the frontal sinus is more of a maneuver than an operation. No definite technique is applicable in all cases, but one's search for the natural opening is facilitated if a certain plan is followed. It is not necessary to remove the anterior portion of the middle turbinate. It is kept intact because of its value as a landmark and as a safeguard against injury to the cribriform plate. The turbinate with its attachment on the outer nasal wall outlines the middle meatus and its removal does not in any way facilitate the search for the opening of the frontal sinus. The anesthetic of choice is a cocaine-epinephrine solution. Cotton saturated with this solution is first placed against the anterior border of the middle turbinate and the nasal wall. After a few moments, this is gently pushed into the middle meatus. Application is next made high up in the meatus by means of a thin, bent applicator. This is allowed to remain until the entire area is anesthetized. The cannula is slipped under the anterior attachment of the middle turbinate with the tip in contact with the outer wall. If the opening is located in this space gentle pressure upward with an occasional rotation medially should bring about success. Failing at this point, the operator should explore the entire area of the frontal recess, gradually maneuvering the cannula backward to its posterior boundary. If the tip of the cannula seems to be constantly in contact with hard bony structures, the search is led to the infundibulum. In those cases in which a continuous channel exists between this groove and the frontal sinus, catheterization is comparatively simple. Contact is made with the bulla as the tip of the cannula passes into the hiatus semilunaris. The tip at first directed outward, is gradually shifted medially as it follows the channel to the sinus. Should the progress of the cannula be stopped almost immediately, it is undoubtedly because the tip has entered the terminal infundibulum cell. The next attempt is made more medial, but in the infundibular area. Associated difficulties however are the various ostia of the infundibular ethmoid cells, which may attract the tip of the cannula in its progress upward. Several attempts may be required before this passageway is safely traversed and the sinus is entered. In case of complete failure, efforts are repeated with the terminal curve of the cannula bent at different angles. The tip of the cannula or probe for that reason should be flexible, for often many bendings take place before an angle is found suitable to the case.

Structural Changes in the Granular Layer of the Cerebellum E. J. Williams New York—p. 206

Experimental Edema.—Shelburne produced hypoproteinemia and edema in two of four dogs fed a diet low in protein for a long time. A critical level of plasma proteins for the formation of edema in the dog is probably 4 Gm of total protein per hundred cubic centimeters and 2 Gm of plasma

albumin The fatty changes in the renal tubules of all the dogs with hypoproteinemia were shown not to be accidental but the result of the experimental procedure. The author was unable to prove that these fatty changes are not due to the anemia which invariably complicates these experiments, but he offers evidence that the anemia is not a potent factor. This fat is not the same as that found in the convoluted tubules in patients presenting the nephrotic syndrome, for in the dogs the fat is not in the form of doubly refractile spherocrystals.

Multiple Necroses of Spleen—Guttman cites a case of flecked spleen in which the anatomic and histologic changes were similar to those reported by Feitis. The kidneys show the lesions of an advanced stage of arteriosclerosis accompanied by arteriolonecrosis. The necrosis is due to occlusion of the splenic arteries of small and medium size. On the basis of the nature of the vascular lesion, three types of flecked spleen are recognized: arteriosclerotic, arteritic and thrombotic. The arteriosclerotic form is the most common, comprising all but three of the twenty-one cases of flecked spleen reported in the literature. The arteriosclerotic form of flecked spleen is associated with renal lesions of hypertension which in most cases produce death from uremia. The thrombotic form, described in a report of a case of eclampsia, is associated with multiple necroses of the kidney. The arteritic type is described in association with two cases of glomerulonephritis. Flecked spleen should be differentiated from multiple necroses of the malpighian corpuscles associated with acute infectious diseases, as the pathologic changes and pathogenesis in the two conditions are dissimilar.

*Injection of Hydroceles with Newer Sclerosing Solutions Experimental Study E Floyd and J L Pittman Atlanta—p 63
Glaucoma J A Smith Macon—p 68

Injection of Hydroceles Experimental Study—Floyd and Pittman made injections in twenty-four cases of hydrocele, using quinine dihydrochloride in one, dextrose and saline solution in two, varisol (a solution containing 30 per cent of invert sugar, 10 per cent of sodium chloride and 1 per cent of benzyl alcohol) in one, glycerin in one and sodium morrhuate in twenty. They used a 5 per cent solution of sodium morrhuate in the majority of their cases because of the uniform results that were obtained with its use in the injection of varicose veins. Recently, however, they added a 0.5 per cent solution of phenol to it. This was done to make it more bactericidal. After preparation of the skin with mercurochrome, a small welt is made with a 1 per cent solution of procaine hydrochloride over the most dependent portion of the sac. A large caliber needle is then inserted into the sac and the fluid is withdrawn. In order to alleviate the initial pain, a 2 per cent solution of procaine hydrochloride is used as a local anesthetic in the sac itself, a small amount being instilled allowed to remain three minutes and then withdrawn. The solution is then instilled. Ordinarily 8 cc. of the fluid is used and is allowed to remain one minute. One half of this amount is withdrawn. A little manipulation is then done and a snug fitting support is applied.

The patient is sent home and for the next few days there is some swelling of the parts. A week later the scrotum feels firm and may contain some fluid. This is usually only a small amount and is absorbed in ten days. The swelling and firmness disappear eventually and the cure is complete within a month. Rarely is palpable induration of the sac present after this period of time. The authors feel that the sclerosing solutions will obliterate the sacs of the acquired, uncomplicated hydroceles. It must be understood that this method is applicable only to selected types of hydroceles.

New Pertussis Antigen—The material for the study of Frawley and his associates represents a cross section of a pertussis epidemic raging in California in the winter and spring months of 1932-1933. Injection of a new pertussis antigen (described by Krueger, Nichols and Frawley) was given to 200 children after exposure or during the course of whooping cough. Thirty-five children received injections after exposure but before any symptoms had appeared. Fourteen did not develop symptoms. Of the twenty-one who went on to clinical pertussis, 76 per cent had a favorable therapeutic response. Of the 165 children first seen during the actual course of the infection, eighty-six had been coughing less than one week, 69 per cent of this group gave good response to treatment, with cessation of severe symptoms in less than a week. Seventy-nine children were seen later than one week after the onset of coughing. Treatment in these was not particularly successful, only 45 per cent showing a cessation of severe symptoms within a week. There was little local and no constitutional reaction. The absence of such reactions would preclude the possibility of any significant incidence of nonspecific response. The authors' series gives evidence of the protective value of the antigen, although this protection is not absolute. Cases treated prophylactically in which the disease developed later presented a definitely modified course.

Recovery from Influenzal Meningitis—Duncan and Webb report complete recovery following adequate spinal drainage in a boy, aged 8, who was one of four children with Pfeiffer bacillus meningitis admitted within the space of a month during the winter of 1932-1933 to the Shreveport Charity Hospital. They state that the available evidence indicates that in the treatment of the disease, as in all forms of nonmeningococcal acute meningitis, it appears that adequate drainage of the cerebrospinal fluid is the one essential. Apparently all the persons who have recovered have had repeated drainages of cerebrospinal fluid, although in many instances various serums and vaccines have been administered by different routes. More efficient drainage of the cerebrospinal fluid by laminectomy has been found valuable in one case of Pfeiffer's bacillus meningitis reported by Martner and Davidson and in two cases of streptococcus meningitis reported by Leighton and Pringle. Recov-

cry followed in all three of these cases. Retan advised the simultaneous intravenous injection of hypotonic sodium chloride solution, producing forced drainage through increased formation of cerebrospinal fluid. The high mortality in all forms of nonepidemic meningitis should stimulate study of all measures that offer hope of success in treating these conditions.

Relation of Urinary Infections to Recurrent Calculi—

According to Keyser, aseptic urinary concretions may be formed in consequence of metabolic errors. Pure uratic, cystine and xanthine stones are known examples. While not definitely proved, calcium oxalate and crystalline carbonate and phosphate calculi may at times have such an origin. Stones composed chiefly of triple phosphate and the amorphous carbonate and phosphate of calcium are formed in alkaline urine probably the result of specific urea-splitting organisms. These are the varieties of calculi most frequent to recur and those which are seen most often in patients with stone-forming kidneys. Therapy directed toward the relief of urostris and clearing up of infection is rational and attended with good result. The mechanism of the formation of urinary concretions as determined by physical chemists and by animal experimentation seems to consist of the coalescence of typical crystals in the gels of urinary colloids.

Cryptorchism with Incidental Carcinoma—Bowen cites a case of cryptorchism because it shows that testicles not in their proper position do not develop proper function and that such atrophic glands tend toward malignant degeneration. Experience has shown that most undescended testicles may readily be brought down into their proper places and develop normally thereafter, if this is done before the age of puberty. This operation is done preferably between the fifth and the tenth year. If they are neglected beyond the age of puberty, removal had best be done under most circumstances. Malignant conditions of the testicle make up about 5 per cent of the malignant changes occurring in man, and approximately 10 per cent of these are found in the undescended gland. They are rapidly growing, fairly early metastasizing tumors, by way either of the lymph or of the blood channels. They usually spread first to the retroperitoneal lymph nodes about the origin of the iliacs and then to those about the kidney pedicle. They then reach the mediastinum and lungs. If they spread by the blood stream,

the lung is, of course, involved earlier. The author believes that, owing to the early stage of the growth in his patient and its apparent complete removal, high voltage roentgen therapy may not have been necessary, but the patient has had three such treatments since his discharge from the hospital. He has gained about 25 pounds (114 Kg) and, except for slight urgency, has no symptoms and feels that he is in good condition.

 *Operation of Sterilization H E Randall Flint —p 74

Operation of Sterilization—Randall has used the following technic since 1921 in 700 sterilizations. No operation should be considered that does not resect both tubes. In a woman a 3 inch low midline incision is made or a Pfannenstiel incision may be used. The finger and thumb of the left hand are introduced into the abdomen, grasping the left ovary and tube. With a small retroflexed uterus it is necessary to use a tenaculum hook to bring the uterus up into the wound. While an assistant makes traction on the tube, a curved pair of hemostatic forceps crushes the horn of the uterus and a curved pair of scissors clips off the horn, it being made certain that the excision is carried down into the uterine muscles. This wound is closed with a number 5 Emmett needle threaded with chromic catgut, then 1½ inches of the tube is excised. A needle is introduced throughout the surface of the broad ligament below the round ligament, which next picks up the proximal end of the tube and the needle is passed back through the broad ligament. By traction of this suture the new proximal end of the fallopian tube is brought into contact with the posterior surface of the broad ligament. The suture is then tied. This operation is repeated on the opposite side. In patients who had borne children this technic occasionally resulted in hemorrhage from the wound in the uterus. In these cases a double salpingectomy is preferable. In the male an incision is made over the vas deferens as it is held between the thumb and finger. The vas feels like a small wire and when reached peels out easily and at least 1½ inches is excised. Interrupted chromic catgut sutures including dartos and skin are inserted and the operation on the opposite vas is done in an identical manner. After-care is ten days in bed in the case of women and a week for men.

Meniscus Sign in Diagnosis of Ulcerating Gastric Carcinoma—Kirklin points out that in gastric ulceration when the lesion is on or near the lesser curvature in the vertical portion of the stomach the ulcer crater is seen roentgenoscopically under palpatory pressure as a crescentic shadow, with its convexity directed outward, and that the term "meniscus" is aptly applied to it. When the lesion is on the lesser curvature distal to the angular incisure, the base of the crater bends with the wall and the meniscus is concave above. If the ulcer is on the posterior wall, the crater appears, under manual pressure over the stomach, as a dense irregularly rounded shadow encircled by a transradiant zone, which corresponds to the elevated border. At the Mayo Clinic in every surgical case in which these manifestations are elicited an ulcerating carcinoma has been found at operation. The author believes that although the meniscus form of the crater as seen in typical cases is important, it seems to him that the slightly raised, overhanging border is even more significant. When the pressure necessary to demonstrate it is exerted over a lesion of this character on the lesser curvature, the crater filled with barium is separated from the barium in the stomach by a clear zone representing the approximated overhanging border of the ulcer. Similarly, when the lesion is on the posterior wall, the marginal ridge surrounding the crater is depicted as an encircling transradiant zone. In either instance the zonal defect is quite as striking as the shadowed crater and distinguishes the lesion from benign ulcer which seldom has a raised or overhanging border. Another mark of the meniscus crater is its slowness in emptying under pressure, and for this the marginal shelf is also responsible. To demonstrate these lesions and determine their character roentgenoscopic examination under manipulation is indispensable. Inspection should begin when the first swallow of barium enters the stomach, and the mixture should be distributed over the gastric walls by palpatory pressure to exhibit the entire mucosal relief. By a downward stroking pressure of the examiner's hand, the meniscus complex of the crater and the encircling ridge can be seen clearly above or between the outspread fingers. The complex is demonstrable not only when the lesions are moderately large but also when they are quite small.

Visualization of Unobstructed Esophagus—To visualize the unobstructed esophagus Wright and Freeman have the subject placed standing in the right anterior position against the upright cassette and instructed to take two or three deep breaths. At the end of a forced expiration the subject is told to swallow two or three mouthfuls of a rather thick barium mixture and as soon as this has been accomplished the roentgen exposures are made that is during suspended respiration. This procedure is repeated two or three times in order that there

may be no misunderstanding and to make sure of satisfactory results. By this method the authors were able in the majority of cases to obtain satisfactory outlines of the filled esophagus and they believe that, if this method is followed carefully, any roentgenologist can produce good roentgenograms of the normal filled esophagus without much practice and with no added expense.

Parathyroid Tumors Associated with Hyperparathyroidism—Churchill and Cope state that the immediate result in their eleven cases, in which a parathyroid tumor has been removed either completely or by subtotal resection, has been a correction of the disturbance in calcium and phosphorus metabolism. In fact, postoperative studies showing the return to normal constitute the final step in establishing the diagnosis and efficacy of the treatment. They are notably lacking in the reported cases of Paget's disease and arthritis. Following removal of the tumor in true hyperparathyroidism, the serum calcium values fall with dramatic rapidity. Symptoms and signs of tetany may appear even with a serum calcium above the normal level when hypercalcemia has been present for a long time. The tetany is controlled by a high calcium diet and by the administration of calcium gluconate, viosterol and parathyroid extract. Improvement in many of the symptoms of hyperparathyroidism may be expected within a few days. In several instances the patient has been made conscious of certain long standing but ill defined symptoms such as loss of energy, constipation or fatigue only by their abrupt cessation following operation. These symptoms are then recognized in retrospect as manifestations of the disease. The muscle and joint pains as well as bony tenderness are promptly relieved. The replacement of calcium in the bones takes a longer time and many months may elapse before any change becomes apparent roentgenographically. The bone tumors being osteoclastomas may be expected to disappear, but the bone cysts formed by fibrous replacement of bone substance persist. How far the kidney damage may be repaired is not known. In certain cases some improvement in renal function has been observed. The only fatality in the eleven cases occurred following the removal of a ureteral stone several weeks after the resection of a parathyroid adenoma. The authors outline the plan of operation and the method of dealing with parathyroid tumors contained in the mediastinum.

Mastopathy and Chronic Mastitis—Whitehouse believes that in chronic mastitis one is dealing with the results of a disorder of function and not primarily with an inflammatory condition. Anomalies in mammary activity occur either as excessive epithelialization of individual acini, as hypersecretion on the part of the mammary lobules or in defective absorption and autolysis of the products of secretory activity. From a study of the whole of the pathologic material in the University of Birmingham classified under "chronic mastitis" and the opinions that the author has formed after an investigation of this and his own material he concludes that 1. It is a matter of importance to correlate the microscopic appearance of the mammary acini and ducts with the period in the menstrual cycle

when the material is obtained. Otherwise what is physiologic may be regarded as pathologic. 2 Abnormalities in the sexual rhythm should be carefully noted, as the same factors that cause irregularities in the menstrual function also produce a typical appearance in the breast epithelium. 3 The condition described as "mazoplasia" is commonly associated in the same organ with the lesion described as "cystiferous hyperplasia." 4 In both lesions epithelial hyperplasia is the preliminary dominant factor and in both lesions the presence of the physiologic lymphocyte in large numbers is a constant factor. 5 Mazoplasia in the adult breast appears to be the natural result of excessive stimulation of the mammary epithelium by the luteal hormone. 6 The result of repeated cyclic excessive stimulation of the mammary epithelium results in the production of excessive secretion and cystic disease. The formation of cysts merely appears to represent a breakdown in the normal balance between production and absorption. 7 Mazoplasia cannot be regarded as entirely physiologic. It is physiologic in the sense that it represents functional activity, but this activity is pathologic and is an indicator of excessive zeal on the part of the physiologic stimulus, either in amount or in concentration. 8 The fluid from mammary cysts is quite definitely a secretion of the mammary epithelium. It also contains colostrum cells and epithelium in process of autolysis. It does not contain fibrin and it does not coagulate. Chemically some specimens show evidence of fat and others contain urea and uric acid. In seventeen of the author's twenty cases of mastopathy both pain and swelling of the breasts disappeared after a few months of treatment with theelin during the premenstrual phase, although the effect was not always manifest after the first or second course of injections. He believes that mastopathy may be relieved and the onset of mammary stagnation prevented by the use of the estrus producing hormone in sufficient quantity to counteract the activity of the corpora lutea.

Operative Lengthening of the Femur—Putti in performing his operative lengthening of the femur has the patient prepared surgically the day before the operation. A Putti operating table is used on which the patient can be maneuvered into the desired position. Under ether anesthesia and iodine preparation of the skin, a Kirchner wire is inserted through the soft parts and the underlying greater trochanter of the femur, in the anteroposterior axis. Another wire is inserted through the supracondylar region of the femur running from the outside in. This wire is inserted in the horizontal plane. A long incision is made over the lateral aspect of the thigh in the middle third and is carried through the subcutaneous tissue, fascia lata and vastus externus down to the shaft of the femur. After closure of the wound and the application of the dressings, the patient is transferred to bed and placed in traction on a Braun frame. The upper wire is firmly fixed to the upper part of the bed by heavy braided wire. Increasing traction is applied to the lower Kirchner wire, beginning with from 7 to 8 Kg (15 to 17 pounds) and from then on, 1 to 2 Kg (2 to 4 pounds) is added daily until the desired lengthening—usually from 2½ up to 4 inches—has been attained. The traction period usually requires from eighteen to twenty-one days. Roentgenograms are made about every third day during the entire period of extension. When the desired length has been attained a sacral rest is inserted under the patient while still in traction, and a spica cast is applied from the costal margin down to the tip of the toes on the side operated on. Little padding is applied and great care should be used in fixing the wires snugly in the cast. The traction remains in place until the cast hardens, then it is disengaged and the patient is moved from the Braun frame onto the bed. Pillows are now used to prop up the limb, which is enclosed in the cast. The wires are usually allowed to remain in place for from three to five more weeks. If a roentgenogram reveals adequate callus formation and the patient is comfortable, the wires are removed. After a few more months another cast is applied with less flexion of the joints and the patient is allowed to get up. Should the roentgenogram reveal inadequate callus, the wires are left in place for a longer period unless signs of infection around the wire are present. The patient requires immobilization from eight to ten months in all. In the eleven cases that the author has treated by this method no complications whatever arose other than a single case of temporary "toe

drop" caused by overstretching of the external popliteal nerve presumably due to faulty position of the knee. The paralysis promptly cleared up with rest and postural treatment.

Trichomonas Vaginalis Vaginitis Treatment with Sodium Perborate—Smith describes a method of treatment that has as its purpose the liberation of gaseous oxygen within the vagina, by the introduction of a compound that is not irritating. The patient makes a suspension of one half tea spoonful of sodium perborate powder in half a cup of luke warm water. This is approximately from 30 to 40 grams (2 to 26 Gm) in from 3 to 4 ounces of water. In the recumbent position she gently injects this freshly prepared suspension into the vagina night and morning and continues this treatment during menstruation. In two or three days the patient experiences marked relief from symptoms and as a rule speaks of a great lessening of the vaginal discharge. It is the author's practice at the first examination to instill into the vagina a little of a 5 per cent solution of mercurochrome on a sponge, although he believes this unnecessary. If the routine is continued for one or two months or through one or two menstrual periods, the patient may stop all injections and be free from symptoms. This treatment, though quite empirical has some theoretical basis. It has been shown that *Trichomonas vaginalis* in cultures is found at the bottom of the test tube and also multiplies under true anaerobic conditions. Cleveland has shown that increased oxygen tension is toxic for a number of parasitic species of *Trichomonas*. Davis states clinically that a speculum examination, merely letting air into the vagina, will make it difficult to find the protozoan parasites in the fresh specimen of the patient's vaginal discharge the next day. Sodium perborate as it comes in contact with exudates gives off bubbles of oxygen, but more slowly than hydrogen dioxide.

Technic for Intrathecal Nerve Root Block—Etherington Wilson outlines a vertical ascent method for intrathecal nerve root anesthesia. A simple sedative is given the night before operation and dextrose within two hours of the operation. The lumbar skin is prepared at the same time as the operative field. One hour before operation the patient is placed on a wheeled stretcher, the ears are plugged with absorbent cotton and the average person should receive $\frac{1}{100}$ grain (0.00065 Gm) of scopolamine intramuscularly. It is often necessary to give a second half dose of scopolamine half an hour later. An intramuscular injection of ephedrine should be given ten minutes before lumbar puncture. The patient is made to sit up across the table and leans forward supported by a nurse. A 20 cc syringe filled with 20 cc of a 1:1,500 solution of nupercaine is inserted, the third lumbar space is punctured and when cerebrospinal fluid appears the stylet is reinserted and the needle is pushed a couple of millimeters farther into the canal by a corkscrew movement. The nurse now makes the patient quite upright, the slow injection is commenced (about fifteen seconds for 10 cc), and at the same time the seconds-hand clock is started. A certain number of seconds is allowed to elapse before the patient is put into the dorsal position; the latter is carried out without any delay, and as the patient reaches this position the table is being sloped head down to an angle of 15 degrees. The average doses and times are 10 cc of nupercaine solution (1:1,500) for low, 12 cc for median and 15 cc for high spinal anesthesia, twenty, thirty and forty seconds are allowed for the upright position, respectively. As the fluid has to travel 6, 9 and 13 inches, it will be seen that nupercaine in these doses is traveling at the rate of about three seconds to the inch. After three minutes at an angle of 15 degrees the patient is raised 5 degrees and is kept at this slope for the remainder of the operation. The author states that he has employed this method successfully in forty-six cases.

*Treatment of Lupus Erythematosus with 'Sanocrysin'. J. L. Franklin—p. 66.

Treatment of Lupus Erythematosus with Gold Compound—Franklin used double thiosulphate of sodium and gold ('Sanocrysin') in treating thirty-one cases of lupus erythematosus. Of these patients twenty were cured, four were improved and seven were resistant to treatment. These results compare favorably with those of other workers. The best results were obtained in those patients who had had the disease for the shortest time. Of the twenty-three patients who had been affected for five years and less eighteen were cured, whereas of the remaining eight patients who had been affected for more than five years only three were cured and three improved. The results also show that the superficial type of the disease is more amenable to treatment with gold salts than the 'fixed' type. Fourteen patients having the superficial type of lupus erythematosus were treated, twelve were cured, one was improved and one was intolerant to the drug but was subsequently cured with another gold compound. Of the seventeen patients with the fixed type of the disease treated eight were cured, three were improved and six did not respond to treatment. The patients who have been cured clinically have been kept under observation for varying periods of time up to two and a half years and although the authors believe that it is too soon to make a statement as to the permanence of the cures there is every reason to believe that those patients who have been healed and who have received thorough treatment will remain cured par-

ticularly those who were affected with the superficial type of the disease. Should relapses occur, however, these patients can usually be given further courses of treatment with the drug. This occurred in one patient who relapsed one year after the end of her first course of treatment and was completely healed after the first three injections of another course of treatment. The first dose should be a small one in case intolerance is exhibited and only exceptionally should a dose of 0.25 Gm be exceeded.

Anaphylactic Basis of Rheumatism—Jenkins points out that the parallelism that exists between the syndromes of the two diseases anaphylaxis and rheumatism and between the drugs used in their treatment are, when itemized, far too numerous to be dismissed as a series of coincidences. There being no other theory that will account for all the phenomena of rheumatism and its treatment he submits that the anaphylactic explanation must be accepted as the only alternative to a position that is no more than a contradictory muddle of mysteries.

Morphologic Studies on Rabies—The prolonged study of a large amount of rabid material of Shortt and Lahiri, including dog, monkey and man has revealed that while characteristic appearances are found in the salivary glands of rabid animals these are in most cases the results of an exaggerated physiologic response of the glands to hyperstimulation and do not necessitate the specific presence of a living virus, although this is probably the cause of the stimulation in rabies. No evidence was obtained of the visible presence of any bodies that could be identified as bacteria, protozoa or filtrable viruses or, indeed, of any living causative agent.

Study on Parasites of Kala-Azar—De describes the different technical methods for the demonstration of the parasites in kala-azar and other leishmania infections and discusses their relative values. The parasites are always found in large

numbers in the liver, spleen and bone marrow and only occasionally in the other parts of the body. The parasites do not remain as freely circulating bodies but are always inside large swollen phagocytic mononuclear cells, the reticulo endothelial cells of Aschoff or the plasmatocytes of Ranvier. The author could not verify the presence of parasites inside the vascular endothelium and he does not see why it should show power of phagocytosis, in view of the fact that vascular endothelium is considered to be a highly specialized tissue very well differentiated functionally. When parasites are present in areas other than the liver, spleen and bone marrow there is usually an inflammatory reaction excited by some cause. The relationship of inflammatory reaction to the infection of the reticulo-endothelial cells by leishmania has been discussed.

Evulsion of Phrenic Nerve in Treatment of Tuberculosis.—Anderson performed phrenic evulsion in fifty-one cases of pulmonary tuberculosis and discusses its indications and results when performed as a preliminary to thoracoplasty in conjunction with artificial pneumothorax and as a sole operative procedure. Twenty-three of his patients when last heard of were alive and well, eleven others were alive, but the outlook in these was still doubtful, sixteen were dead and one was dying. If the series is viewed from the point of view as to whether or not the indication for operation was fulfilled, it is seen that in thirty-six instances the indication was definitely fulfilled, in four it was doubtfully fulfilled and in eleven not at all. When no definite indication for operation existed, no change took place. Phrenic evulsion, whether used as a sole operative procedure or in conjunction with other methods of pulmonary collapse, has a somewhat limited, but still definite and valuable place in the treatment of pulmonary tuberculosis.

Hunger Osteopathy, Juvenile and Late Rickets.—Crawford and Cuthbertson present data derived from a clinical and biochemical investigation of a case of hunger osteopathy, and corresponding observations in cases of juvenile and late rickets (osteomalacia). The essential difference between the metabolism of the case of hunger osteopathy and the rachitic conditions lay in the fact that the former rapidly stored calcium, phosphorus and magnesium without the addition of vitamin D, increased intake of mineral matter leading to increased retention, while on the other hand the rachitic cases only showed retention of mineral matter when vitamin D was added to the diets. The authors consider that hunger osteopathy and late rickets (osteomalacia) are not necessarily identical in their nutritional origin, but that late rickets (osteomalacia) is a form of hunger osteopathy, namely, that due to deficient vitamin D.

Treatment of Angina Pectoris.—Evans and Hoyle observed 122 patients with angina pectoris (angina of effort) over a period of three years with especial reference to the comparative value of vasodilator drugs for the immediate treatment and prevention of attacks. Syphilis was present in twenty-five cases. Coronary thrombosis was considered only a complication. The comparative results show that glyceryl trinitrate in tablet form when absorbed from the mouth is by far the most effective agent for relieving attacks and for their immediate prevention. Of the 122 patients, 86 per cent obtained great relief and a further 11 per cent moderate relief. Other preparations of glyceryl trinitrate and other remedies tried did not give such good results. Glyceryl trinitrate tablets do not cause objectionable symptoms. Amyl nitrite proved to be disappointing for the relief of attacks and it can be recommended only for those rare cases in which glyceryl trinitrate fails. It has the further disadvantage of being useless for the prevention of attacks. The use of glyceryl trinitrate tablets immediately before expected anginal attacks is a safe means of preventing pain and should be used far more widely in routine treatment than it is at present. Of the authors' patients 84.5 per cent obtained great benefit, and a further 12.5 per cent obtained moderate benefit by using the drug in this way. This is a greater measure of improvement than was found when any of the other remedies were tried. Most patients preferred to take the drug at their own discretion, and this method of administration proved more effective than when it was taken at short fixed intervals, except for those patients who could not predict attacks with certainty. No harmful effects were encountered from such treatment, though patients used the drug freely for upward of two to three years, and often this enabled them to take more physical exertion and lead a fuller life than had previously been possible.

Neurovegetative System and Endocrine Glands in Mammary Function—Roussy and Mosinger reviewed the role of the neurovegetative system and the endocrine glands in mammary function. They studied five patients showing a unilateral or predominantly unilateral mammary hyperplasia. In three of these there was marked tenderness to pressure at the point of emergence of the second and third perforating branches. The authors state that the mammary function depends on both the nervous system and the endocrine glands, which often exert a correlated action. Treatment of pathologic galactorrhea is not on an established basis, but they suggest that resection of the fourth intercostal nerve or its perforating branch might give good results.

Pneumothorax and Variation of Altitude—Trocme analyzes the factors involved in changes of altitude on pneumothorax. He believes that they can be expressed in physical formulas and made accessible to calculation. The gaseous pocket of an artificial pneumothorax tends to dilate at increased altitudes by a volume expressed as $\Delta V_M = V \lambda$. V is the initial volume of the pneumothorax and λ a factor dependent solely on the barometric conditions at the points of departure and arrival. Each pneumothorax patient withstands the dilatation differently and exactly as it withstands slow insufflation of the pleura with a like volume ΔV_M . The tension of the pneumothorax is expressed $\Delta t = \frac{\Delta V_M}{\mu}$ where μ is a factor peculiar to

each pneumothorax which shows the usual conditions of capacity and elasticity. The test of the ascension gives a means of calculating the volume of a pneumothorax by the formula $V = \Delta t \times \frac{\mu}{\lambda}$. These facts apply to all closed plant cavities, such as the ear, stomach, and intestine. They thus assume the role of aneroid barometer to the variations in external pressure.

- Treatment of Cerebromeningeal Hemorrhages of the New Born H Slobozianu —p 160

Rôle of Trichomonas Vaginalis in Gynecology—Kissling states that the incidence of leukorrhea and vaginitis due to Trichomonas is high. The presence of Trichomonas may be tolerated without producing any symptom. The existence of Trichomonas is often combined with a vaginitis presenting characteristics and a reaction so specific to treatment that its pathogenic role would never be denied all the more as its disappearance coincides with cure. The frequency of leukorrhea due to Trichomonas is lowered according to age. It attains its maximum between 18 and 35 years of age. The author studied 260 cases of abnormally profuse menstruation 96 of which presented Trichomonas. He found that the usual treatment of leukorrhea by means of vaginal injections of potassium permanganate and of chlorine compounds has no effect. The author cites as the treatment of choice intravaginal administration of pills of chinofon followed by osules of borated glycerin at 5 per cent. This treatment leads to a rapid disappearance of Trichomonas and of the inflammatory symptoms. It is necessary, however, before interrupting treatment to make sure that Trichomonas has definitely disappeared. Relapses after menstruation become constantly less serious, provided treatment is kept up. The relapses are probably due to uncured forms inaccessible to treatment. In only one case

did the author find Trichomonas free from other associations. Most of the time it is found associated with a rich flora of cocci. Many authors report its association with the gonococcus and the author presents two such cases. Like all associations into which the gonococcus enters, this is of short duration. The presence of these parasites may be easily established by Gram's method, gentian violet or Loeffler's methylene blue.

New Management of General Anesthesia—Nitzescu and Iacobovici report favorably on the use of a basal anesthetic consisting of paraldehyde with dextrose. An isotonic solution of dextrose is prepared (566 Gm to the liter). A small amount of this solution is poured into a serum apparatus of from 250 to 300 cc capacity. From 15 to 20 cc of paraldehyde is added with a pipet or sterilized graduate in the proportion of from 6 or 8 cc to 100 cc of dextrose solution. The solution mixes easily on shaking. The solution is injected in the proportion of from 0.15 to 0.21 cc of paraldehyde per kilogram of body weight and at a rate of about 15 or 20 cc a minute. The authors used this method of basal anesthesia in eighty-two patients with good results. The initial irritative stage of induction of general anesthesia was much improved, as was the waking stage. The principal disadvantage of basal anesthesia lies in the inability to remove or alter its effects once the anesthetic is introduced. With paraldehyde prepared in this way the authors feel that the low toxicity and wide margin of safety do much to obviate even this difficulty.

Vesical Ectopy—In twenty-five years, Monnier treated nine cases of vesical ectopy. He reviews therapeutic methods that have been recommended and reaches the conclusion that the Coffey-Mayo method is the best. In this procedure the ureters are severed before their entrance into the bladder, the peripheral section is closed by a ligature and the oral portion is transplanted obliquely into the sigmoid. An ascending infection is prevented if implantation is done in such a manner that from 4 to 5 cm of the ureter passes between the mucosa and the musculature. Thus the intra-intestinal pressure closes the implanted section so that backflow is impossible. Another advantage of the operation is that the technic is so simple that it can be performed on young children. Eventually it can be done in two stages. A complication developing in one of the cases in which the author employed the Coffey-Mayo method, convinced him that the following factors should be given attention. 1 The ureters should be mobilized only as far as it is

absolutely necessary, so as not to impair their nutrition. The preparatory treatment of the intestine should be taken care of. In order to secure an aseptic implantation, the technical suggestions of Coffey should be followed, that is during the operation the inside of the intestine should be treated with irrigations and tamponade and the anastomosis should be done with closed mucous membrane and with a suture which after it has been cast off will establish a connection between intestine and ureter.

Serologic Maturation Processes and Latent Immunity—The Hirszfelds point out that the irregular susceptibility of various races for pathogenic micro organisms and observations on families and on twins indicate that the constitution plays a part in infectious diseases. However because of the multiplicity of internal and external factors it is difficult to recognize the constitutional principle. In the Schick test for diphtheria the Brokman test for dysentery and the Dick test for scarlet fever, the negative skin reaction is generally ascribed to the presence of antitoxins but the authors point out that the predisposition of the tissues must be given consideration. They assume that there are forms of immunity which can be traced to a deficiency in the reaction capacity. With the aid of the skin reactions racial differences have been demonstrated in the susceptibility for diphtheria and scarlet fever. Other investigations demonstrated an increase in the antitoxin carriers with advancing age. The problem is whether this increase is due to a spontaneous development of the antibodies or to latent immunity. The authors investigated several cutaneous reactions. They reach the conclusion that the development of epidemics is largely dependent on the number of susceptible persons. In case of high virulence of the pathogenic micro organism the constitutional factors are of minor significance but if prolonged contact of the pathogenic micro organism and the macro organism has produced a mutual habituation the constitutional differences in susceptibility play an important part.

Otitis Media and Diarrhea in Children—Clinical analysis of the acute diarrheas in more than 100 children by Brokman showed that the principal symptoms were otitis media, diarrhea, disturbances in the intermediate metabolism and disturbances of the central nervous system. Pathologic, bacteriologic and serologic investigations corroborated the clinical unitarian theory. A number of disease entities which so far were considered otogenous sepsis, atypical alimentary intoxication or atypical dysentery have become a unit. The primary etiology is still unknown and the pathogenesis has been cleared only partly but this point of view is an attempt to form a new clinical, therapeutic and epidemiologic foundation for these serious disturbances occurring in small children.

Painful Paralysis of Arm of Young Children—Feer describes a painful paralysis of the arm which develops in small children after slight traumas. The condition occurs comparatively often but as a rule only in children less than 5 years of age. The trauma that causes the condition often develops in the following manner: A child is led by the hand and stumbles but in order to avert a fall the person leading the child pulls the arm. The child cries and the arm hangs limp as if paralyzed. Touching of the arm and attempts at movement are painful. It has been determined on the cadavers of children that by a jerking pull on the hand the arm can be brought into a position similar to this form of painful paralysis. In this condition the head of the radius has slipped partly out of the annular ligament and the ligament is incarcerated between the radius and the humerus. This explains the great painfulness of all movements in the elbow joint. On the cadaver, the adjustment of the head of the radius and of the annular ligament could be accomplished by supination and flexion of the forearm. The condition has been designated as perannular radial subluxation or as subluxation of the radius by elongation. It is identical with the so called painful paralysis of young children.

Spontaneous Pneumothorax in Nurslings—Will relates the clinical histories of three nurslings with spontaneous pneumothorax. All three showed a good general development in spite of the early appearance and persistence of the pneumothorax. The most important clinical symptoms are dyspnea

contraction of the thorax and displacement of the heart. Typical changes in the physical aspects of the lung do not become manifest until later. Roentgenoscopy reveals less density on the side of the pneumothorax and displacement of the heart and the mediastinum toward the opposite side, the yieldingness of the so called weak site being especially pronounced. In case of a left-sided pneumothorax, a massive collapse of the right upper lobe becomes manifest. The diagnosis is made more difficult by faint pulmonary outlines in the regions of lesser density and by the indistinct margins of the collapsed lung. Puncture and the determination of the pressure are of great significance for the diagnosis. Measurements of the pressure in the described cases indicated that the assumption of a hyperpressure of a tension pneumothorax was not justified. In one of the cases the measurements revealed a negative intrathoracic pressure, but in spite of this there was an enormous displacement of the heart and of the mediastinum. This seems to indicate that merely a pressure difference between the two halves of the thorax is sufficient to produce a great displacement of the mediastinum. In the differential diagnosis, massive pulmonary collapse, atelectatic pneumonia, cystic and honeycombed lung and hypoplasia of the lung have to be considered. The prognosis is doubtful because of the danger of chronic bronchitis and of bronchiectasis. Treatment does not promise great results, for conservative measures do not counteract the pneumothorax and puncture produce only temporary results. If the child shows a fairly good development, the parents are usually reluctant to give their consent to an intervention. The author considers a congenital pulmonary defect the probable cause of the spontaneous pneumothorax in children.

Polichinico, Rome

Pneumothorax Treatment of Pulmonary Gangrene. G. Dalla Torre—p. 157

Modification of Takata-Ara Test—Lazzaro performed Jezler's modification of the Takata-Ara test in 200 cases. Nine small tubes are prepared and 1 cc of the 0.9 per cent physiologic solution of sodium chloride is placed in each tube. To the first tube is added 1 cc of the liquid to be examined (serum or ascitic fluid). 1 cc of this mixture is pipetted off and added to the second tube. The same procedure is repeated in the other tubes until there is a series of dilutions of from 1:2 to 1:512. To each tube is added 0.25 cc of a 10 per cent solution of sodium carbonate and 0.3 cc of the reagent of Takata, which is prepared at the moment of use by mixing equal parts of a 0.5 per cent solution of corrosive mercuric chloride and a 0.2 per cent aqueous solution of fuchsin. The tubes are kept at room temperature and corked. After six and twenty-four hours respectively the reaction is determined. The reaction is positive in serum if there is a flocculation in at least three tubes and if the first flocculation is observed in a dilution of 1:32 or in a higher dilution. The reaction is positive in the ascitic fluid if the first flocculation appears in a dilution of 1:8 or higher. The reaction is weakly positive if the flocculation shows in a dilution of 1:32 or 1:8 in two tubes, and if it is scarcely evident in the third tube from either end. In twenty normal persons the reaction was constantly negative, it was negative in sixty patients presenting pernicious anemia, hemolytic icterus, gastric and duodenal ulcer, leukemic myelosis, diabetes mellitus, typhoid malaria, exudative pneumonia, pulmonary tuberculosis, cardiac diseases and croupal pleurisy. Of twenty-nine cases of cirrhosis of the liver, twenty-four showed a positive, four a weakly positive and one a negative reaction. In two cases of severe catarrhal icterus the reaction was positive during the acute period of the disease and became negative during convalescence. In cases evincing a positive reaction the increased globulin content was lower than 1. The inversion of the increased globulin content does not necessarily determine the possible outcome of the reaction, as many diseases show inversion of the content and a negative reaction.

Nicotine in Ulcer Disease—Friedrich believes that the role of nicotine in the etiology of ulcer disease has been rather underestimated. Ulcer disease, especially the prepyloric ulcer, has been on the increase since the war. This increase has been predominantly in men. There has likewise been a steady increase in the consumption of tobacco. The author investigated 153 men who were operated on for ulcer disease and found that 79.7 per cent of them were pronounced smokers, averaging from twenty to thirty cigarettes a day. Studies of the effect of nicotine on the tonus of the splanchnic vessels and the motility and secretion of the stomach demonstrated that it is capable of altering the normal course of gastric function. The postoperative results were better in persons who smoked but little or not at all before the operation, when contrasted with those who were heavy smokers even after the operation. Nicotine was found to influence the gastric function in the postoperative period as well. In addition to the effect of nicotine swallowed with the saliva and absorbed from the oral mucosa and the mucosa of the respiratory passages a reflex effect must be taken into consideration. The author believes that irritation of the mucous membrane of the mouth results in a reflex stimulation of gastric secretion. Thus smoking may be compared to sham feedings with the resultant flow of gastric juice which cannot be utilized. The recent studies of Buchner and Moskowicz showed that such gastric juice is dangerous even for the healthy cells. It would appear therefore, that smoking on an empty stomach is particularly damaging.

Inflammatory Reactivity in Surgical Operations—Ebhardt points out that the inflammatory reaction of the skin is taken as the measure of defense mechanism of the body. Studies in allergy demonstrated that the skin occupies a prominent position as a general reactive organ. The method of study consisted in applying to the leg a cantharides plaster for twenty-two hours. The contents of the blister resulting from the cantharides irritation were then studied as to the cellular content. The response to cantharides irritation on the part of the skin is regarded as a mobilization of the reticulo endothelial cells of the skin. In observations made on uncomplicated appendectomies in the surgical clinic of the University of Greifswald the author noted that the first stage of the cantharides exudate presented a suppurative character and was regularly followed by a transition to a lymphohistiocytic type of cells. Eosinophils did not appear earlier than the sixth postoperative day. A postoperative rise in cells was noted in practically all cases. In appendicitis of longer duration, several days the increase in the number of cells may fail to take place and transition to the lymphohistiocytic type may be delayed, and the eosinophils, as a rule, will appear immediately after the operation. The later complications of appendicitis are more clearly reflected in the inflammatory cell picture than in the temperature curve or the blood picture. A return to the suppurative reaction takes place. The course in conservatively treated perforative appendicitis was characterized by a suppurative reaction in the febrile state which in the course of encapsulation and absorption of the pus gradually shifted to the lymphohistiocytic phase. The study of various subacute chronic infections showed a constant increase in lymphohistiocytes, with a tendency to fluctuations as pronounced as from 10 to 70 per cent. The conclusion was drawn that the more the mesenchyma participated in the defense mechanism the stronger was the histiocytic reaction in the rest of the organism and also in the skin. The author thinks that the occasional remarkable

effect of an exploratory operation in tuberculous peritonitis may be ascribed to the stimulation of the reticulo endothelial system. Stimuli and irritants influence the cantharides exudate by mobilizing the histiocytes and the eosinophils. The effect of an operation or of injury on a normal organism is one of an unspecific irritant and is followed by a typical reaction in two phases, the leukocytic combative and the lymphohistiocytic convalescent phases. The author concludes that repeated studies in the course of a surgical disturbance of the cantharides exudate offer a valuable biologic method of estimating the cellular defense mechanism.

Dermatologische Zeitschrift, Berlin

 Gonorrheal Lymphangitides Originating in Distant Metastases Problem of Rarity C Carrie —p 252
 *Experimental Herpetic Folliculitis Percutaneous Inoculation with Herpes and Problem of Natural Tissue Infection H Hruszek —p 258

Epidermophytides and Epidermophytin—The development of epidermophytides and the positive outcome of the intra-dermal epidermophytin reaction are cited by Ruete and Scholz as proof that epidermophytosis is not merely a superficial disturbance. They found that vaccination with epidermophytin (filtrate from epidermophyton cultures) gave positive results in 100 per cent of the patients with epidermophytosis. Moreover, the reaction seems to be specific for epidermophytosis, for it was negative in a form of trichophyton infection and in pityriasis versicolor. However, further tests will be necessary to demonstrate the specificity definitely. The experiences with the immunoreaction induced the authors to try the therapeutic application of epidermophytin. They treated fifteen patients by means of epidermophytin wheals and effected prompt cures. The injections are not painful. With the exception of a slight itching, they produce no undesirable sensations and no fever. The authors cite case reports, which indicate that the injections hasten the frequently prolonged course of the disorder and that in combination with iodine and a sulfonated bitumen powder they may replace the unpleasant treatment with ointments.

Experimental Herpetic Folliculitis—Hruszek shows that the manifestations which have been traced to the herpes virus are manifold. As the port of entry of the herpes virus and the mechanism of its first infection has not been fully explained as yet, the author made studies with percutaneous inoculation. Inoculation of human skin was accomplished by rubbing it with human herpes material. A typical herpetic folliculitis developed. The herpetic nature of the folliculitis was demonstrated on the cornea of rabbits and in further human passages by means of scarification. The further development of the herpes that was produced by rubbing herpes material into the skin and its tendency to successive crops and to relapses were identical with those of the herpes that had been produced by scarification. The author thinks that there are perhaps other forms of simple herpes in which a herpetic etiology has not been thought of. He mentions particularly follicular dermatoses (according to Naegeli some cases of "nonparasitic" sycosis) that do not necessarily have to present a vesicular monomorphic picture but may appear also as papules, urticarial efflorescences and pustules.

- *Acetonemic Convulsions During Childhood Significance of Hypoglycemia G Fanconi —p 1
 Postvaccinal Disturbances W Blacher —p 26
 Second Attacks and Relapses in Acute Infectious Diseases of Childhood H Zischinsky —p 43

Acetonemic Convulsions During Childhood Significance of Hypoglycemia—Fanconi describes seven cases of acetonemic convulsions. Gastro-intestinal disturbances particularly lack of appetite and vomiting preceded the attacks by at least several hours. Diarrhea was absent in some cases and constipation existed. The convulsions were preceded by an aura. The first attack lasting several minutes did not complete the picture but an epileptic state developed and between

the attacks the children were either in a coma or were somnolent and apathic. The condition differs from true epilepsy in the rapid succession of the attacks and in the prolonged stupor, and, whereas true epileptic attacks generally develop during the night or on awakening these acetoneic convulsions developed during the day. The temperature was increased during the convulsions. The urine contained acetone and acetic acid but the sugar test was negative. The cerebrospinal fluid was normal, with the exception of the increased sugar content that characterizes all convulsive states. Examination of the blood revealed unusually low sugar values during the coma and the convulsions in spite of the fact that the patient had received sugar either by mouth or parenterally. After several days the blood sugar returned to normal. In dextrose tolerance tests that were performed immediately after the cessation of the convulsion the blood sugar increased hardly at all but the subsequent decrease to normal or subnormal values was extraordinarily pronounced. Tolerance tests that were made later gave mostly normal results. The author concludes that in the carbohydrate hunger that develops following gastrointestinal disturbances the normal child protects itself against hypoglycemia and its sequels (convulsions and so on) by limiting the insulin production. The child with acetoneic convulsions fails to do this, and in this deficient regulation of the insular apparatus the author sees the cause of spasmophilia. He recommends an easily digestible diet with high carbohydrate but low fat and protein content. During the comas dextrose should be administered. If a child has had an attack of acetoneic convulsions the parents should see to it that it never fasts for longer periods and even during diarrhea and fever the child should be given sufficient amounts of sugared tea and fruit juices.

Therapeutic Action of Diphtheria Serums.—The failure of diphtheria antitoxin in certain cases has been ascribed to different causes. The theory has been advanced that the rapidly flocculating serums and those which in the test tube neutralize toxins rapidly have a greater therapeutic value. Kolle and Prigge decided to investigate this problem. They reach the conclusion that the acidity (neutralization and flocculation speeds) of the diphtheria serums exerts no noticeable influence on the therapeutic action. They maintain that the results of the serotherapy of diphtheria depend primarily on the time at which the serum is administered. The earlier after the onset of the infection the serum is injected, the better are the prospects for a cure.

Disturbances in Vascularization of Skin Simulating Leukoderma.—Dietel describes peculiar whitish spots that give the impression of circumscribed areas of depigmentation, which occurred more frequently during the cold season. The incidence and the extent of the disorder were greater in women than in men. In many of the patients there existed a tendency to acrocyanosis. The irregularly distributed whitish spots, which vary in size but do not exceed that of a pea appear as a rule on the backs of the hands and on the forearms. If the arms are stretched upward for a while the spots tend to disappear. Obliteration of the spots can be accomplished also by the production of active hyperemia for instance by prolonged rubbing, hot baths and so on, but, as soon as the irritation

subsides, they reappear. Cold baths produce a bluish red coloration of the skin and an intensification of the spots. It was demonstrated that the whitish spots always reappear at the same site. The author considers them the result of disturbances in the vascularization of the skin. The cause is apparently a vascular spasm in a precapillary arteriole, so that the apparent depigmentation is probably nothing but an ischemic area. To a certain extent the condition is related to cutis marmorata, but it differs from the latter in that the reticular patterns are absent. The author thinks that the whitish spots are often the result of slight degrees of freezing. In the majority of cases the condition involves the hands and arms, but one case is described in which the spots appeared on the legs of a girl, aged 15, who had been in the habit of going without stockings. The author suggests the term "pseudoleukoderma."
